

Water Resources Study Report

Bad Creek Pumped Storage Project

Oconee County, South Carolina

1 Project Introduction and Background

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir and Lake Jocassee, which is licensed as part of the Keowee-Toxaway Hydroelectric Project (FERC Project No. 2503), as the lower reservoir.

The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977, and expiration date of July 31, 2027. The license has been subsequently and substantively amended, with the most recent amendment on August 6, 2018, for authorization to upgrade and rehabilitate the four pump-turbines in the powerhouse and increase the Authorized Installed and Maximum Hydraulic capacities for the Project. Duke Energy is pursuing a new license for the Project pursuant to the Commission's Integrated Licensing Process, as described at 18 Code of Federal Regulations (CFR) Part 5.

In accordance with 18 CFR §5.11 of the Commission's regulations, Duke Energy developed a Revised Study Plan (RSP) for the Project and proposed six studies for Project relicensing. The RSP was filed with the Commission and made available to stakeholders on December 5, 2022. FERC issued the Study Plan Determination on January 4, 2023, which included modifications to one of the six proposed studies. Duke Energy completed its first year of studies in 2023 with stakeholder consultation as required by the Commission's SPD. Duke Energy filed the Initial Study Report (ISR) on January 4, 2024, and per the Commission's regulations at 18 CFR §5.15(c), Duke Energy held an ISR meeting with participants and FERC staff within 15 days of filing the ISR on Wednesday, January 17, 2024. Duke Energy completed its second and final year of studies in 2024, filed the Updated Study Report (USR) [18 CFR §5.15(c)] January 3, 2025, and held the USR meeting on January 16, 2025. This report describes the Licensee's methods and results of the studies conducted in support of preparing an application for a new license for the existing Project and construction of the proposed Bad Creek II Power Complex (Bad Creek II).

2 Water Resources Study

2.1 FERC Environmental Resource Issues

The Commission issued Scoping Document 2 on August 5, 2022, which identified the following environmental resource issues to be analyzed in the National Environmental Policy Act (NEPA) document for the Project relicensing related to water resources. These resource issues address the effects of continued Project operations as well as potential construction and operation of Bad Creek II during the new license term:

- Effects of construction-related erosion, sedimentation, and spoils disposal on water quality, aquatic habitat, and aquatic biota in Lake Jocassee and streams in the Project vicinity.
- Effects of Project operation on water levels in Lake Jocassee.
- Effects of Project operation on water quality in Lake Jocassee, including water temperature, dissolved oxygen (DO) concentrations, and vertical mixing of DO.
- Effects of reservoir fluctuations associated with Project operation on aquatic habitat and biota in Lake Jocassee.
- Effects of vertical mixing of DO associated with Project operation on fish populations in Lake Jocassee.

The Water Resources Study focused on historical water quality data of Lake Jocassee, potential impacts to surface waters due to construction of Bad Creek II, and water resources affected by a second inlet/outlet structure in the Whitewater River arm of Lake Jocassee, while the Aquatic Resources Study evaluated impacts associated with aquatic life and habitat. The Water Resources Study is complete, and this report presents methods and results of the individual study tasks.

2.2 Study Goals and Objectives

Tasks carried out for the Bad Creek Water Resources Study employ standard methodologies consistent with the scope and level of effort described in the RSP. The goal of the Water Resources Study is to evaluate the Project effects, as well as potential effects or impacts due to the construction and operation of the proposed facility using existing and new information; it is intended to provide sufficient information to support an analysis of the potential Project-related effects on water resources, as well as potential effects or impacts due to the construction and operation of Bad Creek II. The main objectives of this study are as follows:

- To evaluate water resources and water quality impacts of current Project operations using existing data.
- To evaluate water resources and water quality impacts potentially resulting from the construction and operation of Bad Creek II.
- To address stakeholder concerns regarding water resources in the Project Boundary with clear nexus to the Project and Bad Creek II.

Objectives of the Water Resources Study were met through five competed study tasks listed in Table 1 below.

3 Report Layout

The Water Resources Study is complete and final task reports have been developed in consultation with the Water Resources Resource Committee; individual task reports are attached to this report as shown in Table 1. Documentation of consultation with the Resource Committee regarding the Water Resources Study is presented in Attachment 6.

1 Project Introduction and Background

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir (Upper Reservoir) and Lake Jocassee, which is licensed as part of the Keowee-Toxaway (KT) Hydroelectric Project (FERC Project No. 2503), as the lower reservoir.

The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977 and expiration date of July 31, 2027. The license has been subsequently and substantively amended, with the most recent amendment on August 6, 2018 for authorization to upgrade and rehabilitate the four pump-turbines in the powerhouse and increase the Authorized Installed and Maximum Hydraulic capacities for the Project. Duke Energy is pursuing a new license for the Project pursuant to the Commission's Integrated Licensing Process, as described at 18 Code of Federal Regulations (CFR) Part 5.

In accordance with 18 CFR §5.11 of the Commission's regulations, Duke Energy developed a Revised Study Plan (RSP) for the Project and proposed six studies for Project relicensing. The RSP was filed with the Commission and made available to stakeholders on December 5, 2022. FERC issued the Study Plan Determination on January 4, 2023, which included modifications to one of the six proposed studies (Recreational Resources Study).

This report includes the findings for Task 1 (Summary of Existing Water Quality and Standards) of the Water Resources Study. The Water Resources Study is ongoing in support of preparing an application for a new license for the Project in accordance with 18 CFR §5.15, as provided in the RSP.

2 Study Goals and Objectives

Tasks carried out for the Bad Creek Water Resources Study employ standard methodologies that are consistent with the scope and level of effort described in the RSP filed with the Commission on December 5, 2022. This report was developed in support of Task 1 of the Water Resources Study (Summary of Existing Water Quality Data and Standards) and is intended to provide sufficient information to support an analysis of the potential Project-related effects on water resources with clear nexus to the Project.

The main goal of this desktop review is to compile previously collected water quality data and provide a summary of existing data from Lake Jocassee and Howard Creek under current Project operations and prior to Project operations, while addressing stakeholder concerns.

3 Study Area

The study area for the desktop review of existing water quality data includes Lake Jocassee (i.e., the lower reservoir) and Howard Creek (Figure 3-1), a tributary to Lake Jocassee that flows in a southeasterly direction along the downstream side of the Project dams. These are the waterbodies potentially impacted by the Project².

² Note that water quality monitoring in the Bad Creek Reservoir is not safe (due to rapid, large fluctuations in water level elevation and typically continuous Project operation) nor is it considered meaningful, given the short retention time of Bad Creek Reservoir. Due to pumping and generating cycles, retention time is approximately 3 days if only a single pump-turbine unit is operating. There are no existing water quality data in the Upper Reservoir; it is used only for Project operations and there is no public access.

Note: NHD = U.S. Geological Survey (USGS) National Hydrology Database

Figure 3-1. Study Area for Desktop Review of Lake Jocassee and Howard Creek

4 Description of Project Waters

4.1 Overview

The Project is located in the Blue Ridge physiographic province in the headwaters of the Savannah River basin. The Savannah River basin has an area of approximately 10,577 square miles (mi²) and drains portions of the Blue Ridge, Piedmont, and Coastal Plain regions.

The Project uses the Bad Creek Reservoir as its upper reservoir, which has a drainage area of approximately 1.5 mi². Construction of the Project began in December 1985 and major work was completed by December 1990 (see Table 4-1); initial filling of the Bad Creek Reservoir began in January 1991. Prior to impoundment, Bad Creek and West Bad Creek were tributaries of Howard Creek (a tributary to Lake Jocassee) located near the toe of the Main Dam and West Dam, respectively. Howard Creek flows from its headwaters (northwest of the Project) and through the southern border of the Project Boundary with a drainage area of approximately 4.3 mi² at its downstream confluence with Limber Pole Creek. Seepage through the two earthen dams now flows into Howard Creek near the toe of each dam. Average seepage flows from the Main Dam and the West Dam are approximately 5.0 cubic feet (ft) per second (cfs) combined. Water from Bad Creek Reservoir is exchanged directly with Lake Jocassee. Due to the small drainage area of Bad Creek Reservoir, inflows are minimal and have limited to no effect on water quality or Project operations.

Lake Jocassee, which operates as the lower reservoir for the Project, was formed by impounding the Keowee River at river mile 343.6, just downstream of the confluence of the Whitewater and Toxaway rivers. Lake Jocassee has a drainage area of 145 mi², a surface area of approximately 7,980 acres, and approximately 92 miles of shoreline at full pond (1,110 ft above mean sea level [msl]). Water from Lake Jocassee flows directly into Lake Keowee, which was formed by impounding the Keowee River and the Little River, and the two impoundments are connected through an excavated canal creating one large impoundment. Duke Energy has monitored water quality conditions in Lake Jocassee in some capacity since the reservoir's formation in 1973.

During Project construction, excavated rockfill was hauled to the western shore of Whitewater River cove (also called Whitewater River arm), transported out into the lake on barges, and placed in the water to construct an underwater weir approximately 1,800 ft downstream of the

Project inlet/outlet (I/O) structure (weir midpoint coordinates 35.0015, -82.991509). The existing submerged weir is approximately 567 ft wide and 455 ft long with a crest elevation of approximately 1,060 ft msl. It was installed to help minimize the effects of Project operations on the natural stratification of Lake Jocassee and dissipate the energy of the discharging water from the Project's I/O structure.

For reference, Table 4-1 includes a list of significant construction (or other) events at the Project.

 Table 4-1. Bad Creek Project Construction or other Significant Events

Date	Event		
October 30, 1984	Project access road construction begins

September 1991	Commercial operation – Unit 3 and 4		
August 16-17, 1994	Tropical Storm Beryl		

4.2 Water Quality Standards and Use Classifications

North Carolina and South Carolina have assigned state water quality standards commensurate with a designated use of a waterbody and both states have similar categories of designated use. Some of the tributaries flowing into Lake Jocassee are wholly within North Carolina, some are wholly within South Carolina, and some flow through both states. Variations of sub-sets of general classifications between the two states exist; however, both states have recognized and distinguished between general use to maintain and support aquatic life and general contact recreation, trout habitats, and high value resource areas.

Under the authority of the South Carolina Pollution Control Act, the South Carolina Department of Health and Environmental Control (SCDHEC) Water Classification & Standards establishes appropriate water uses and protection classifications, as well as general rules and specific water quality criteria to protect existing water uses, establish anti-degradation rules, protect public welfare, and maintain and enhance water quality. Streams with the following Water Classifications are found in the Project vicinity: Outstanding Resources Waters (ORW); Trout Natural (TN); and Trout Put, Grow, and Take (TPGT). The Whitewater River is classified as ORW, Howard Creek is classified as TN, and Whitewater River tributaries are classified as ORW and TPGT (SCDHEC 2021; NCDEQ 2021). Lake Jocassee is designated as TPGT. TPGT waters are freshwaters suitable for supporting growth of stocked trout populations and a balanced indigenous aquatic community of fauna and flora. These waters are also suitable for contact recreation and as a drinking water supply source after conventional treatment. A summary of the designated use classifications for the Lake Jocassee watershed is provided in Table 4-2. Note the only waterbodies considered in this report are Lake Jocassee and the portion of Howard Creek downstream of the Project dams.

Table 4-2. Surface Water Classifications of Waterbodies within Lake Jocassee Watershed

Devils Hole Creek	SC	The entire creek tributary to Lake Jocassee	TPGT
Jackie's Branch	SC	The entire creek tributary to Lake Jocassee	TN
Mill Creek	SC	The entire creek tributary to Lake Jocassee	TPGT

^{*} Evaluated in this report

Sources: SCDHEC 2020, 2021; NCDEQ 2021

A summary of water quality standards for South Carolina applicable to Project waters (i.e., Blue Ridge; trout waters) is included in Table 4-3. Note that nutrient criteria (i.e., phosphorous, nitrogen, chlorophyll a) in the state of South Carolina apply only to lakes and reservoirs, not rivers and streams. Numeric nutrient criteria are based on an ecoregional approach which takes into account the geographic location of the lake and are applicable to lakes of 40 acres or more (SCDHEC 2020). In evaluating the effects of nutrients on the quality of lakes and other waters of the state, SCDHEC may consider, but not be limited to, such factors as the hydrology and morphometry of the waterbody, the existing and projected trophic state, characteristics of the loadings, and other control mechanisms to protect the existing and classified uses of the waters (SCDHEC 2020).

Table 4-3. South Carolina Numeric State Water Quality Standards for Parameters
Assessed in Project Waters

Parameter	South Carolina Water Quality Standard	
Temperature (applies to heated effluents only)	Not to exceed 2.8°C (5°F) above natural temperatures up to 32.2°C (90°F) Trout Waters: Not to vary from levels existing under natural conditions, unless determined some other temperature shall protect the classified uses	
Dissolved Oxygen	Daily average not less than 5.0 milligrams per liter (mg/L) Instantaneous low of 4.0 mg/L Trout Waters: Not less than 6.0 mg/L	
рН	Between 6.0 and 8.5 Trout Waters: between 6.0 and 8.0	
Turbidity	Freshwater Lakes Only: Not to exceed 25 NTUs provided existing uses are maintained.

Parameter	South Carolina Water Quality Standard	
	Trout Waters: Not to exceed 10 NTUs or 10% above natural conditions, provided existing uses are maintained.	
Phosphorus	Blue Ridge – Shall not exceed 0.02 mg/L. Piedmont – Shall not exceed 0.06 mg/L.	
Nitrogen	Blue Ridge – Shall not exceed 0.35 mg/L. Piedmont – Shall not exceed 1.5 mg/L.	
Chlorophyll a	Blue Ridge – Shall not exceed 10 μg/L. Piedmont – Shall not exceed 40 μg/L.	

Source: SCDHEC 2020

4.3 Compliance with SCDHEC State Standards

One important goal of the Clean Water Act, the South Carolina Pollution Control Act, and the State Water Quality Classifications and Standards is to maintain the quality of surface waters to provide for the survival and propagation of a balanced indigenous aquatic community of fauna and flora (SCDHEC n.d.). The degree to which aquatic life is protected is assessed by comparing important water quality characteristics and the concentrations of potentially toxic pollutants with numeric criteria. Support of aquatic life uses is determined based on the percentage of numeric criteria excursions and, where data are available, the composition and functional integrity of the biological community (SCDHEC n.d.).

South Carolina water quality standards and thresholds are listed above in Table 4-3. The SCDHEC assessment methodology (SCDHEC n.d.) states that grab samples or samples collected at a depth of 0.3 meters are considered to be a surface measurement; this is consistent with Duke Energy's surface measurement methods. For the purpose of assessment, only surface samples are used in standards comparisons and trend assessments (SCDHEC n.d.). Note that the SCDHEC and U.S. Environmental Protection Agency (USEPA) do not define the sampling method or frequency of sampling for water quality to compare to criteria, other than indicating it should be "representative" (SCDHEC n.d.).

For temperature and dissolved oxygen (DO) standards, if the percentage of criterion excursions is greater than 10 percent, but less than or equal to 25 percent, the criterion is partially supported. If the percentage of criterion excursions is 10 percent or less across the dataset, the criterion is said to be fully supported (SCDHEC n.d.).

For turbidity, phosphorus, total nitrogen, and chlorophyll a, if the individual criterion is exceeded in more than 25 percent of the samples, the criterion is considered not supported. If the criterion is exceeded in more than 10 but less than 25 percent, sites are evaluated on a case-by-case basis to determine if local conditions indicate that classified uses are impaired. If the criterion is exceeded in less than 10 percent of the samples, the criterion is considered fully supported (SCDHEC n.d.).³

5 Lake Jocassee

Lake Jocassee is classified as an oligotrophic waterbody exhibiting low productivity, low nutrient concentrations, and high clarity. Generally, DO concentrations (as well as percent DO saturation) remain relatively high due to the low productivity (slow consumption of oxygen due to limited biological activity and benthic decomposition rates) (Dobson and Frid 2009). It is a monomictic lake experiencing seasonal thermal stratification (summer) and mixing (winter); however, the lake's geomorphological characteristics sometimes result in minor mixing between the upper and lower levels of the water column, allowing for thermal stratification to persist for several years without turn-over (Duke Power Company 1995).

Lake Jocassee is included in the highest water quality classification (i.e., excellent rating) as designated by SCDHEC and preservation of existing conditions is recommended, with most tributaries within the watershed fully supporting their designated use. It is one of only a few reservoirs in South Carolina possessing the necessary aquatic habitat (water temperature and DO) to support both warmwater and coldwater (salmonid [trout]) fisheries year-round (USACE 2014). SCDHEC has consistently identified Lake Jocassee, as well as downstream Lake Keowee, among the cleanest South Carolina reservoirs based on previous data and recent data continue to indicate Lake Jocassee fully supports aquatic life and recreational designated uses (USACE 2014).

³ Note that the goal of the standards for aquatic life uses is the protection of a balanced indigenous aquatic community; therefore, biological data are the ultimate deciding factor, regardless of chemical conditions. If biological data show a healthy, balanced community, the use is considered supported even if chemical parameters do not meet the applicable criteria (SCDHEC n.d).

5.1 Data Analysis Methods

Water quality datasets for Lake Jocassee were received directly from Duke Energy's Environmental Science Group in July 2022 (Microsoft Excel®). Methods for water quality data collection, calibration, data entry, and quality control have followed Duke Energy standard operating procedures (SOPs) and guidelines, which have been reviewed and updated periodically since inception of the environmental monitoring program. Duke Energy's most recent water quality monitoring SOPs are the Duke Energy Water Quality Field Procedure (ESFP-SW-0503, Rev1) and the Duke Energy Water Chemistry Sample Collection ESFP-SW-0504, Rev0), which are included for reference in Appendix A.

To satisfy the objective of summarizing existing water quality conditions and comparing them to conditions that existed prior to Project construction, Lake Jocassee water quality data were pooled and separated into two time periods: pre operations and post operations. Because Units 1 and 2 began commercial operation in March 1991 (see Table 4-1), the post operation period (also called post construction period) is 1991-2020. The start year for data from the pre operation/pre construction period is not consistent between monitoring stations but on average, data measurements began in the late 1970's. The pre operation period is considered any year prior to 1991.

Vertical water column measurements were averaged for every 15-foot interval for each month of the year⁴ to show average seasonal trends for each of the following water quality parameters:

- Temperature (degrees Celsius [°C])
- Dissolved oxygen (mg/L)
- Dissolved oxygen percent saturation (%)
- pH (Standard units)
- Phosphorus (mg/L)
- Nitrogen (mg/L)
- Chlorophyll a (mg/L)
- Conductivity (microsiemens per centimeter [μS/cm])

⁴ Winter months include December through February, spring is March through May, summer is June through August, and fall is September through November.

Water quality data are summarized in Section 5.3 and accompanying detailed data tables are provided in Appendix B for depth and surface-averaged measurements for individual monitoring stations shown on Figure 3-1.

Because water in the Whitewater River arm is directly exchanged with waters of the Upper Reservoir, a separate water quality analysis was carried out for three existing monitoring stations in the Whitewater River cove since those stations are most impacted by Project operations (Stations 564.1, 564.0, and 560.0 shown on Figure 5-1). For the Whitewater River cove analysis, a third time period covering the years during Project construction (1985-1991) was evaluated in addition to pre and post construction.

Turbidity values (vertical profiles) were also assessed at the three Whitewater River cove locations to identify; (1) potential relationships between past project construction activities (or other external drivers such as major storms) and increased turbidity, (2) downstream extent of turbidity impacts in Whitewater River cove, and (3) approximate length of time for elevated turbidity levels to recover. Turbidity data are compiled and presented in a format that shows pre construction, construction, and post construction conditions. This information can be used to help inform future potential water quality/turbidity impacts due to the potential construction of Bad Creek II.

FD3

5.2 Water Quality Monitoring Stations

Twelve water quality monitoring stations have been routinely measured by Duke Energy over the last 40 years (Figure 3-1). Depth-averaged and surface data are included in Appendix B for each station. Periods of record for each monitoring station are provided in Table 5-1. Minimum reading elevations⁵ (ft msl) at each monitoring station are also presented in Table 5-1. Normal maximum pond elevation is 1,110 ft msl and normal minimum pond elevation is 1,080 ft msl.

Table 5-1. Water Quality Monitoring Station Periods of Record

Monitoring station	Start Year	End Year	Minimum Reading Elevation (ft)
558.7	1987	2015	763
558.0	1975	2020	757
559.0	1987	2015	793
560.0*	1975	2015	826
562.0	1980	2015	965
565.4	1987	1994	918
551.0	1975	2011	1083
564.0*	1976	2015	865
564.1*	1987	2017	960
557.0	1975	2015	820
554.8	1986	2015	945
556.0	1975	2015	918

^{*}Whitewater River arm

As stated previously, water quality at Stations 564.1, 564.0, and 560.0 in the Whitewater River arm were assessed separately over three periods since those locations are most impacted by Project construction and operation due to proximity. The data from these stations also provide information on the function of the submerged weir. Additionally, turbidity values are summarized at the three monitoring stations in the Whitewater River arm (discussed in Section 5.3.8).

5.3 Water Quality Summary Results

5.3.1 Temperature

Water temperature dictates the types of biota that can survive in a waterbody, affects metabolic rates and photosynthesis, influences the rates of chemical reactions, and impacts the physical

⁵ Minimum reading elevations are at or near the reservoir bottom for each monitoring station.

capacity of water to hold DO. Water temperature is also important because of its influence on water chemistry; the rate of chemical reactions generally increases at higher temperatures (USGS 2018a). Thermal stratification in a lake is a seasonal phenomenon that occurs from late spring to late fall in temperate regions. In the summer, the uppermost layer of water is warmed by the sun and cooler water in the lower water column begins to separate from the top, resulting in a warmer layer of water at the top (i.e., epilimnion) and a heavier/denser layer of water at the bottom (i.e., hypolimnion). The thinner layer that separates the warmer upper waters from the cooler bottom waters is the metalimnion or thermocline, which acts as a barrier that prevents mixing and heat exchange between the epilimnion and hypolimnion. During winter, there is usually little temperature stratification as the entire lake cools. In Lake Jocassee, the depth of the thermocline varies between locations in the lake (based on depth and geomorphology) as well as between seasons.

Because temperatures at depth determine patterns of stratification (i.e., warmer water in the upper water column, cooler water at depth), depth-averaged temperatures were assessed during this desktop review as well as surface water temperatures. Over the entire reservoir at all depths, Lake Jocassee winter temperatures range between 0 and 17°C, with an average of 10°C. Thermal stratification is not prevalent in the winter months (December – February) and at some stations, February temperatures vary by less than one degree between surface and bottom waters. Spring temperatures range from 5 to 25°C with an average of 11°C. Stratification begins to form in the upper third of the water column as temperatures continue to warm towards late spring. Summer temperatures range from 7 to 30°C with an average of 15°C. Stratification continues to develop through summer and extends further down into the water column. Fall temperatures range from 7 to 28°C with an average of 15°C. Stratification peaks in early fall and begins to wane as temperatures cool. All data tables showing temperatures and patterns of stratification for each monitoring station are included in Appendix B.

Bad Creek operational impacts to temperature are limited to monitoring Station 564.1 in the Whitewater River cove, which is between the I/O structure and submerged weir (see Figure 5-1). Monthly average temperatures within the water column at this location are nearly uniform after 1991 (post Bad Creek operation) (Figure 5-2). Vertical mixing from Bad Creek operations eliminates any stratification at this monitoring station regardless of season. The pre construction

depth-averaged temperature at Station 564.1 is 13.9°C, and the post construction average temperature at Station 564.1 (through 2017) is 17.2°C, a difference of 3.3°C.

Monitoring Station 564.0 (see Figure 5-3) is located downstream of the submerged weir and in contrast to Station 564.1, stratification is prevalent at this location after 1991. There is very little difference in temperature profiles between pre and post Bad Creek operations at Station 564.0. This is primarily due to the presence of the submerged weir, which limits mixing downstream of the weir structure (i.e., mixing is confined to the portion of the Whitewater River cove upstream of the submerged weir).

Tables of monthly averaged temperature profiles for pre and post Bad Creek operational conditions at each of the 12 monitoring locations are provided in Appendix B. Additionally, tables of data showing depth-averaged temperatures for pre construction, construction, and post construction in the Whitewater River arm indicating changing stratification trends are included in Appendix B.

Figure 5-3. Station 564.0 Downstream of the Weir Showing Temperature Stratification for **Pre and Post Operations**

Surface water temperature minimum, average, and maximum values for all stations over the entire dataset are included in Table 5-2. Discrete water quality data assessed in Lake Jocassee consistently met South Carolina water quality standards for trout waters for temperature. There is no numeric threshold for temperature, however, for trout waters, narrative criteria indicate water temperatures should not vary from levels existing under natural conditions (unless determined some other temperature shall protect the classified uses), which is supported by study findings.

A comparison of pre vs. post operations for surface water at each station is provided in Table 5-3 and average surface water data are included in Appendix B. There is no clear trend in warming from pre to post operations in surface waters and temperature differences are mostly within one degree. It is important to note that surface waters are affected by ambient air temperature, therefore, any elevated temperatures under present-day conditions may be impacted by climate warming over the last three decades.⁶ It is noteworthy that surface waters at Station 564.1 do not indicate the warmer temperatures noted at depth between pre and post operation periods (i.e., - 0.8°C change at the surface but +3.3°C change at depth, indicative of the I/O structure at depth).

Table 5-2. Water Temperature in Surface Waters of Lake Jocassee

Lake .	Jocassee Surface T	Cemperature (degr	ees C)
Station	Minimum	Average	Maximum
558.7	8.20	18.59	29.02
558.0	7.10	18.44	28.22
559.0	8.10	18.81	28.90
560.0	7.10	18.87	28.47
562.0	8.10	19.23	29.20
565.4	8.50	18.84	28.50
551.0	0.20	13.48	27.24
564.0	7.40	19.15	28.61
564.1	8.50	18.99	28.40
557.0	7.10	18.81	29.23
554.8	7.70	19.24	29.15
556.0	7.30	19.04	29.12

⁶ A climate assessment is beyond the scope of this desktop study, however, a summary of climate trends in the region will be assessed and reported in the license application.

Table 5-3. Average and Standard Deviation of Surface Temperatures, Pre vs. Post Operations

Monitoring		Tempera	ture (°C)		
Station	Pre ope	erations	Post op	erations	Difference of
	Average	Standard Deviation	Average	Standard Deviation	Averages

5.3.2 Dissolved Oxygen

5.3.2.1 Dissolved Oxygen Concentration

Dissolved oxygen is a measure of how much oxygen is dissolved in the water and is the amount of oxygen available to living aquatic organisms. The concentration of DO in surface water is affected by temperature and has both a seasonal and a daily cycle. In winter and early spring, when water temperature is low, DO concentrations are typically higher as cold water can hold more DO than warm water. In summer and fall, when the water temperature is high, the DO concentration is often lower (USGS 2018b). Similar to temperature, DO typically shows patterns of stratification in large, deep reservoirs like Lake Jocassee. Just after summer stratification is established, the hypolimnion is rich in DO from the early spring mixing of the lake. However, because the metalimnion acts as a barrier between the epilimnion and hypolimnion, the hypolimnion is essentially cut off from oxygen exchange with the atmosphere and the deepest parts of the lake can become hypoxic (i.e., DO concentrations less than 2 mg/L) to anoxic (i.e., depleted of oxygen). Lake Jocassee is very deep in some places, and it is not unusual for DO to be depleted at depth. Because near-surface waters are used by most forms of aquatic life, DO concentrations measured at the water surface or in near-surface waters are used to assess the health of a waterbody (instead of DO at depth). Because depth-averaged values are not

considered when determining the health of the waterbody (i.e., SCDHEC standards only apply to water at the surface as explained in Section 4.3), these data are provided for context, however, average surface water values are also provided below for each season and as minimum, maximum, and average for each station in Table 5-4. All data (depth and surface) are included in Appendix B.

The position of the thermocline varies from location to location and between seasons, as is typical for large, deep reservoirs, therefore, an overall trend of DO values are provided herein. Lake Jocassee winter DO concentrations (throughout the water column) are between 0 and 14 mg/L, with an average of 7 mg/L. In deeper portions of Lake Jocassee, winter DO stratification is characterized by a rapid decline in DO in the lower half of the water column, with the upper half generally at constant values. The average winter surface (i.e., measurement depth 0.3 meter) DO over the entire dataset is 9.4 mg/L. Winter stratification is less prevalent in shallower portions of the lake.

Spring DO concentrations range from 0 to 13 mg/L with an average of 8 mg/L. DO concentrations remain consistent throughout the spring months and some stratification is present in the deepest sections of the lake. Average spring surface DO (0.3 m) is 9.7 mg/L.

Summer DO concentrations range from 0 to 13 mg/L with an average of 7 mg/L. Stratification becomes more pronounced throughout the lake with the transition from spring into summer. This stratification is generally limited to the lower half of the lake in both deep and shallow areas. Average summer surface DO is 8.2 mg/L.

Fall DO concentrations range from 0 to 11 mg/L with an average of 6 mg/L. The most notable stratification pattern is seen in the fall where the bottom of the lake can reach anoxic levels. DO concentrations remain constant in the top third of the water column, however, significant stratification is observed in the lower water column. Average fall surface DO is 8.1 mg/L.

Tables of monthly averaged DO profiles for pre and post Bad Creek operational conditions at each of the 12 monitoring locations are provided in Appendix B. Additionally, tables of data showing depth-averaged DO values for pre construction, construction, and post construction in the Whitewater River arm to show changing stratification trends over time are included in Appendix B.

Similar to trends in temperature data, Bad Creek operational impacts to DO are limited to monitoring Station 564.1 between the I/O structure and submerged weir. Monthly average DO concentrations within the water column at this location are nearly uniform after 1991 (post Bad Creek operation) (Figure 5-4). Vertical mixing from Bad Creek operations does not allow for stratification at this monitoring location regardless of season.

DO stratification does occur at monitoring Station 564.0 (downstream of the weir), and there is very little difference in DO profiles between pre and post Bad Creek operation indicating the submerged weir is functioning as intended (Figure 5-5).

In general, DO concentrations in Lake Jocassee are a function of the extent of the previous winter mixing – colder winter temperatures result in deeper mixing within the reservoir, which results in higher DO concentrations the following year (USACE 2014). Multiple droughts over the reservoir's history have resulted in maximum drawdowns up to 29 ft (USACE 2014); however, the overall thermal structure of the reservoir helped to maintain DO concentrations throughout the water column and were not impacted by the drawdown events (i.e., reduced water elevation), indicating even under extreme drought conditions, DO remains above state threshold levels throughout Lake Jocassee (i.e., 6.0 mg/L) (USACE 2014).

Figure 5-5. Station 564.0 Downstream of the Weir Showing Stratification for Pre and Post Operations

The state standard for DO in trout waters is > 6.0 mg/L (instantaneous minimum). Before 1991 there were two instances of surface DO less than 6.0 mg/L: 4.6 mg/L at monitoring Station 558.0 in 1973 and 5.4 mg/L at monitoring Station 556.0 in 1976, which correspond to the first few years after the reservoir was filled in 1973. There were no instances of surface DO values less than 6.0 mg/L after 1991. Average surface water data are included in Appendix B.

Over the entire dataset, there were 4,241 surface measurements assessed; a total of five measurements were below the state standard, which accounts for 0.12 percent of the dataset (Table 5-4). Therefore, surface water DO concentrations in Lake Jocassee fully support the designated use classification (i.e., less than 10 percent criterion excursions).

Lake Jocassee Surface DO (mg/L) Station Minimum Average Maximum 558.7 6.8 8.7 11.2 558.0 4.6 8.7 11.2 559.0 6.9 8.7 11.1 560.0 6.1 8.7 11.8 562.0 6.9 8.8 11.3 565.4 7.4 8.8 11.2 551.0 7.2 9.9 14.4 564.0 6.6 8.8 12.2 564.1 6.6 8.6 11.1 557.0 6.7 8.9 11.6 554.8 6.7 8.9 11.2 556.0 5.4 9.0 11.6

Table 5-4. Dissolved Oxygen in Surface Waters of Lake Jocassee

5.3.2.2 Dissolved Oxygen Saturation

Dissolved oxygen saturation is reported in units of percent and represents the percent of oxygen that has dissolved into water (a value typical of a given temperature). Percent saturation is indicative of the percentage of oxygen dissolved in water at a given temperature and gas pressure. Equilibrium is indicated by 100 percent saturation with higher temperatures decreasing oxygen solubility)⁷. Supersaturation, or saturation greater than 100 percent, may be observed in a reservoir as a result of the photosynthetic process by phytoplankton and other aquatic plants

⁷ https://www.waterboards.ca.gov/water_issues/programs/swamp/docs/cwt/guidance/3110en.pdf

that may be present. Conversely, saturation less than 100 percent in a reservoir can be a function of microbial respiration from decomposition of organic matter.

Lake Jocassee winter DO saturation ranges from 100 percent at the surface to 0 percent at the bottom of the water column. The average winter surface (measured at 0.3 m) DO saturation is 87.2 percent. DO saturation remains constant in the upper top half of the lake and decreases from about 80 percent saturation to near anoxic levels at the reservoir bottom.

The average lake-wide spring surface DO saturation is 98.6 percent. Spring has the highest average DO saturation; spring DO saturation decreases relatively uniformly with depth, with the deepest sections of the lake generally dropping from 100 percent at the surface to 50 percent saturation at the lake bottom.

The average lake-wide summer surface DO saturation is 101.3 percent. Similar to spring values, DO saturation decreases uniformly with depth, but more sharply, generally decreasing from 100 percent at the surface to 35 percent at the lake bottom.

The average lake-wide fall surface DO saturation is 91.5 percent. As expected, fall continues the trend of decreased saturation in the lower portions of the water column, becoming anoxic near the lake bottom.

Dissolved oxygen saturation depth profile tables are provided in Appendix B (DO saturation sampling began in 1998, i.e., post Bad Creek operations) at each of the 12 monitoring stations. Additionally, depth-averaged DO percentages for pre construction, construction, and post construction in the Whitewater River arm are included in Appendix B. While no data exist prior to operations, stratification between the stations in Whitewater River cove is apparent.

Dissolved oxygen percentage in surface samples are shown in Table 5-5. There is no state standard for DO saturation, however, since Lake Jocassee supports a diverse, healthy fish community, it is assumed percentage of DO saturation is suitable for aquatic resources.

DO Saturation (%) Station Minimum Average Maximum 558.7 65.80 93.98 108.50 558.0 68.20 106.00 93.63 559.0 94.30 62.70 109.80 560.0 53.30 93.75 107.70 562.0 66.50 96.59 112.70 565.4 551.0 85.80 95.51 100.80 564.0 58.30 93.84 107.20 564.1 63.00 92.27 108.20 557.0 67.80 95.99 109.60 554.8 74.80 97.26 111.90 556.0 74.00 97.04 110.80

Note: (--) indicates no DO saturation data were collected at Station 565.4

5.3.3 pH

The pH level of a waterbody is a measure of hydrogen ion concentration and is ranked on a scale of 1 (acidic) to 14 (basic). This water quality parameter affects many chemical and biological processes in the water and different organisms have different ranges of pH within which they flourish (USGS 2019). The relationship between phytoplankton and daily pH cycles is well established. Photosynthesis by phytoplankton consumes carbon dioxide during the day, which results in a rise in pH. In the dark, phytoplankton respiration releases carbon dioxide. In productive lakes, carbon dioxide decreases to very low levels, causing the pH to rise (SCDHEC n.d.). Note that the pH of a given waterbody is predominantly determined by the soil and rock type in the area. Surface waters in mountain streams in the vicinity of Lake Jocassee are typically poorly buffered and tend to have low pH values (Abernathy et al. 1994).

Typical Lake Jocassee pH values range between 5 and 10 (averaged throughout the water column) with an average of 6.2, which is considered neutral and indicative of a system with low production (i.e., little potential for algal growth). There is very little difference in pH between seasons and while there is some variation in the water column, there is very little to no pH stratification. Similar to temperature and DO trends, pH concentrations at monitoring station 564.1 are well mixed as a result of Bad Creek operations. Just downstream of the submerged

weir at monitoring Station 564.0, there is some pH variation in the water column post 1991 as the submerged weir limits vertical mixing at this location. pH profiles at this monitoring location are similar pre and post Bad Creek operations. Tables of monthly averaged pH depth profiles for pre and post Bad Creek operational conditions at each of the 12 monitoring locations are provided in Appendix B.

Surface pH values for all stations are included in Table 5-6 and average surface water data are included in Appendix B. Instantaneous pH surface readings were compared against the pH state standard for trout waters (6.0-8.0 Standard Units). Over the entire dataset, there were 4,253 samples assessed; a total of 2 samples were above the state standard (i.e., less than 1 percent of the dataset) and 255 samples were below the state standard (i.e., 6 percent of the dataset). Therefore, surface water pH levels in Lake Jocassee fully support the designated use classification (i.e., within 10 percent criterion excursions).

Surface Phosphorous (Standard Units) Station Minimum Average Maximum 558.7 5.50 6.67 7.60 558.0 5.20 6.56 8.00 559.0 5.30 6.67 7.71 560.0 5.60 6.69 7.80 562.0 5.60 6.76 7.90 565.4 5.60 6.50 8.10 551.0 5.50 6.53 7.90 564.0 5.60 7.90 6.78 564.1 5.60 6.73 7.90 557.0 5.50 6.73 7.80 554.8 5.60 6.84 8.10 556.0 5.63 7.90 6.80

Table 5-6. pH in Surface Waters of Lake Jocassee

5.3.4 Phosphorus

Phosphorus is a common constituent of agricultural fertilizers, manure, and organic wastes in sewage and industrial effluent; too much phosphorus in a waterbody can speed up eutrophication (a reduction in dissolved oxygen in water bodies caused by an increase of mineral and organic nutrients) (USGS 2018c). Because Lake Jocassee is not in a predominantly agricultural or industrial setting, phosphorus values are typically low.

Lake Jocassee phosphorus concentrations at depth range from 0.002 to 0.68 mg/L with an average of 0.01 mg/L. Tables of monthly averaged depth profiles for pre and post Bad Creek operational conditions at each of the 12 monitoring locations are provided in Appendix B. As with other water quality parameters, mixing due to Bad Creek operations creates relatively constant profiles of phosphorus in the water column at monitoring station 564.1.

Table 5-7 below shows a summary of phosphorus for the surface waters of Lake Jocassee over the entire dataset and surface water data tables are included in Appendix B. The state standard for total phosphorous in lakes and reservoirs in the Blue Ridge region of South Carolina shall not exceed 0.02 mg/L.

Over the entire dataset, there were 2,228 surface samples assessed; a total of 228 samples were above the state standard, which accounts for 9.8 percent of the dataset (Table 5-7). Therefore, surface water phosphorus concentrations in Lake Jocassee fully support the designated use classification (i.e., less than 10 percent criterion excursions).

Surface Phosphorous (mg/L) Maximum Station Minimum Average 558.7 0.002 0.007 0.100 558.0 0.002 0.011 0.650 559.0 0.002 0.008 0.056 560.0 0.002 0.009 0.081 0.002 0.009 0.037 562.0 565.4 0.002 0.012 0.082 551.0 0.0050.015 0.100564.0 0.002 0.009 0.057 564.1 0.002 0.011 0.165 557.0 0.002 0.010 0.087 554.8 0.002 0.010 0.057 556.0 0.002 0.009 0.061

Table 5-7. Phosphorus in Surface Waters of Lake Jocassee

5.3.5 Nitrogen

Similar to phosphorus, too much nitrogen (in the forms of nitrate, nitrite, or ammonium) can cause a number of adverse effects. Excess nitrogen can cause overstimulation of growth and aquatic plant and algae. Total Kjeldahl Nitrogen (TKN) is a measure of organic nitrogen (i.e., naturally occurring) and ammonia in a water sample and provides a way to quantify the amount

of nitrogen contained in organic form (USGS 2018e). Nitrate (NO₃) is the product of aerobic transformation of ammonia and is the most common form of nitrogen used by aquatic plants while nitrite (NO₂) is usually not present in significant amounts (SCDHEC n.d.). Total nitrogen is the sum of TKN and NO₂+ NO₃.

The dataset for total nitrogen is limited in Lake Jocassee relative to other water quality parameters. Of the nearly 2,000 measurements recorded for NO₂ and NO₃, there are only 545 readings where TKN was measured, therefore, the dataset for total nitrogen includes 545 datapoints. Tables of monthly averaged total nitrogen depth profiles for pre and post Bad Creek operational conditions at each of the 12 monitoring locations are provided in Appendix B.

Table 5-8 below shows a summary of total nitrogen for the surface waters of Lake Jocassee over the entire dataset and surface water data tables are included in Appendix B. The state standard for total nitrogen for lakes and reservoirs in the Blue Ridge region of South Carolina shall not exceed 0.35 mg/L. Over the entire dataset, there were 545 surface samples assessed; a total of 33 samples were above the state standard, which accounts for 6.1 percent of the dataset⁸ (Table 5-8). Therefore, surface water total nitrogen concentrations in Lake Jocassee fully support the designated use classification (i.e., less than 10 percent criterion excursions).

Table 5-8. Total Nitrogen in Surface Waters of Lake Jocassee

Lake Joc	assee Surface	Total Nitroge	en (mg/L)
Station	Minimum	Average	Maximum
558.7	0.11	0.23	0.56
558	0.11	0.23	0.59
559	0.14	0.26	0.78
560	0.11	0.23	0.55
562	0.13	0.24	0.56
565.4	0.13	0.21	0.47
551	0.12	0.16	0.20
564	0.11	0.22	0.51
564.1	0.18	0.22	0.34
557	0.11	0.21	0.54
554.8	0.12	0.21	0.48
556	0.11	0.22	0.53

⁸ Note that of the 33 total nitrogen excursions, only one excursion was caused by elevated inorganic nitrogen; the remaining excursions were due to elevated organic nitrogen (i.e., TKN), which is naturally occurring.

5.3.6 Chlorophyll a

Chlorophyll allows plants (including phytoplankton [algae]) to photosynthesize, i.e., use sunlight to convert simple molecules into organic compounds. Chlorophyll a is the predominant type of chlorophyll found in green plants and is a surrogate for the amount of algae growing in a waterbody; it can be used to classify the trophic condition of a waterbody (USEPA 2022b). One of the symptoms of degraded water quality condition is the increase of algae biomass as measured by the concentration of chlorophyll a. Typically, increased chlorophyll a is a result of external nutrient inputs from surface runoff from agricultural areas with fertilizers, septic systems, sewage treatment plants, and urban runoff (USEPA 2022a). However, the Lake Jocassee watershed is largely undisturbed (i.e., forested), therefore, does not have these input sources. Rather, chlorophyll a concentrations in Lake Jocassee stem from internal loading of phosphorus from inside the lake. As stratification develops during the summer months, cooler oxygenated water settles to the bottom of the reservoir. The oxygen is consumed over the summer and fall months due to the decomposition of organic matter and uptake from fish. When this happens, it triggers the release of phosphorous from the organic matter and sediments at the bottom of the reservoir. Because Lake Jocassee is oligotrophic (i.e., high dissolved oxygen, lower amounts of organic matter, and low levels of phosphorus), phosphorus input from internal loading does not significantly increase the total phosphorus levels (or chlorophyll a concentrations) in Lake Jocassee. Tables of monthly averaged chlorophyll a depth profiles for pre and post Bad Creek operational conditions at each of the 12 monitoring locations are provided in Appendix B.

Table 5-9 below shows a summary of cholorphyll a for the surface waters of Lake Jocassee over the entire dataset and surface water data tables are included in Appendix B. The state standard for chlorophyll a for lakes and reservoirs in the Blue Ridge region of South Carolina Shall not exceed 10 μg/L. Over the entire dataset, there were 1,753 surface samples assessed; all samples were below the state standard, which accounts for 100 percent of the dataset (Table 5-9). Therefore, surface water chlorophyll a concentrations in Lake Jocassee fully support the designated use classification (i.e., less than 10 percent criterion excursions).

5.3.7 Conductivity

551.0

564.0

564.1

557.0

554.8

556.0

Conductivity is a measure of the ability of water to pass an electrical current; because dissolved salts and other inorganic chemicals conduct electrical current, conductivity increases as salinity increases, therefore it is an indirect measure of the saltiness of the water (USEPA 2022b). Conductivity is also directly related to rainfall runoff events as tributary inflows to Lake Jocassee carry these dissolved salts and inorganic chemicals from the watershed into the reservoir. Since rainfall is consistent through the year in the region, conductivity values in Lake Jocassee do not vary seasonally but do increase during periods of higher rainfall runoff. For example, during drier periods, conductivity in Lake Jocassee is very low ranging from 2.0 to 5.0 μ S/cm. During wetter periods, conductivity ranges from 85.5 to 275 μ S/cm. The overall annual average conductivity in the reservoir was approximately 18.1 μ S/cm.

Similar to the other water quality parameters, conductivity values at monitoring station 564.1 on the upstream side of the submerged weir are well mixed due to Bad Creek operations. Downstream of the submerged weir at monitoring station 564.0, there is some variability in conductivity throughout the water column but the conductivity profiles at this location are similar pre and post Bad Creek operations indicating limited vertical mixing due to the submerged weir.

Tables of monthly averaged conductivity profiles for pre and post Bad Creek operational conditions at each of the 12 monitoring locations are provided in Appendix B⁹.

Table 5-10 below shows a summary of conductivity for the surface waters of Lake Jocassee over the entire dataset and surface water data tables are included in Appendix B. While there is no state standard for specific conductivity, concentrations less than 500 μ S/cm are generally considered to be suitable for aquatic species in southern Appalachian waters (USEPA 2020). The maximum surface conductivity measured was 34 μ S/cm and the minimum was 2.0 μ S/cm (Table 5-10); since Lake Jocassee supports a diverse, healthy fish community, it is assumed this range of conductivity is suitable for aquatic resources.

Table 5-10. Conductivity in Surface Waters of Lake Jocassee

5.3.8 Turbidity

Turbidity is a measure of the amount of suspended particles in water (quantified by the amount of light scattered) and is typically measured in Nephelometric Turbidity Units (NTU). While turbidity is not an inherent property of water like temperature and DO, it is recognized as an indicator of environmental health of a waterbody (USGS 2018d). Turbidity levels in a waterbody are typically episodic in nature and are not spatially or temporally consistent. Generally, turbidity

⁹ Erroneously high conductivity readings at or near the lakebed were removed from the dataset as the conductivity measuring device likely impacted the lakebed, stirring up sediment leading to false readings.

values in a river or lake increase proportionally with increased suspended sediment in the water column. Under natural conditions, suspended sediment load contribution to a receiving waterbody increases during a rainstorm/runoff event where sediment is eroded from upland areas or stream banks and flows into surface waters. Another major contributor to upland soil/sediment erosion is construction activities; these activities are often short-lived but can result in large amounts of soil released from the land that is subsequently transported to adjacent waterbodies. Depending on the magnitude of the rain event, amount and grainsize of sediment, proximity to the point of entry, and character of a waterbody, sediment can settle out quickly after the event or may remain suspended in the water column for some time after the event, resulting in prolonged elevated turbidity, which can be detrimental to aquatic habitat. Because turbidity is simply the amount of light that can pass through water, turbidity values can increase due to any solid particles in the water, including organic material and microscopic organisms.

During original Project construction, waters of the Whitewater River cove were directly impacted by construction activities. Historical turbidity data in the Whitewater River cove at three monitoring stations (see Figure 5-1) were evaluated to determine if original construction activities resulted in a noticeable increase in turbidity values and if so, estimate how far downstream impacts extended and for how long turbidity was elevated; this was done by comparing turbidity values from (1) pre construction (<1985), construction (1985-1991)¹⁰, and post construction (1992-2015) (see Table 5-11).

In general, turbidity data were collected once per month, however, there are notable gaps in datasets (several months or years at a time) depending on the station. Measurements were taken at varying depths along the vertical profile (i.e., varied between collection events). Data gaps and vertical depth measurement locations are shown on the turbidity data plots provided in Appendix C. Note that turbidity does not show spatial trends or patterns of stratification such as temperature and DO; turbidity measurements represent a snapshot in time and are typically driven by external factors, therefore, data points do not need to be contiguous in space or time for confidence in interpretation. Where it was obvious that a dataset had a falsely elevated

¹⁰ Duke Energy is considering expanding the existing submerged weir with newly excavated rockfill from the proposed Bad Creek II Complex in part to help mitigate the impacts of a second I/O structure in Whitewater River cove. Assessing pre construction turbidity data and estimating impacts to turbidity during original construction may help inform water quality conditions during proposed construction of the Bad Creek II Complex.

bottom reading (due to resuspension of bed sediment) or an erroneously high measurement in the water column when compared with data above and below it, values were removed from the dataset. Of 6,682 data points, 28 data values were removed, representing less than 1.0 percent of the dataset.

Station Pre construction **During construction** Post construction 564.1 N/A Jan 1988 – Dec 1991 Jan 1992– Jan 2015 564.0 Aug 1976 – Oct 1985 Feb 1986 - Dec 1991 Jan 1992 – Jan 2015 Sept 1973 - Oct 1985 560.0 Feb 1986 - Dec 1991 Jan 1992 – Jan 2015

Table 5-11. Monitoring Stations and Years of Data

5.3.8.1 Results

Turbidity results are summarized by monitoring station in the sections below. To evaluate turbidity impacts at depth, this parameter was evaluated throughout the water column. Three sets of turbidity figures are provided in Appendix C for each of the three monitoring stations and include;

- Turbidity values vs. lake elevation and year for pre construction, construction, and post construction periods (three separate figures);
- Turbidity values vs. lake elevation and year for the full dataset;
- Depth-averaged turbidity values compared to the 10 NTU state standard.

5.3.8.1.1 Station 564.1

As mentioned previously, Station 564.1 is located just downstream of the Project I/O structure and immediately upstream of the submerged weir. This station receives direct inflow from the Whitewater River and is approximately 45 meters (148 ft) deep. Details of data from Station 564.1 are provided in Table 5-12. Turbidity was not measured at Station 564.1 until January 1988, therefore, there is no pre construction dataset. During the construction period, when elevated turbidity values were observed, they were elevated consistently in the water column on the same days (i.e., rather than randomly in the water column or across many different days); this likely indicates episodic events contributing increased sediment to the area (e.g., construction activities). In general, turbidity values were elevated lower in the water column vs. near the surface on all days where elevated turbidity values were observed. The depth-averaged turbidity reading at this station during the construction period was 18.5 NTU with a standard deviation

[stdev] of 51 NTU, indicating significant variance in the dataset. The dataset from Station 564.1 contains the highest turbidity values from any period or monitoring station. There were three notable instances where turbidity was elevated for several readings in a row:

- January September 1988 (average 65 NTU); the first two readings at this station (January and February 1988) had the highest values at 476 NTU (Jan) and 202 NTU (February). Consistently elevated readings over a nine-month period are likely the results of construction activities. These values continued to decrease each month from March through September.
- July December 1990 Nine consecutive readings with an average of 26 NTU over the nine readings.
- April August 1989 (average 25 NTU).

Additionally, there was one measurement on February 21, 1990, with elevated turbidity; however, because elevated turbidity values were not noted in the measurements before or after this day, this was likely due to a rain event or very short-lived construction event.

Under post construction conditions, turbidity values at all depths averaged 0.8 NTU (stdev 2.0). The maximum turbidity level measured during this time was 28 NTU.

• There were seven measurements that exceeded the state standard of 10 NTU over the post construction dataset. Six of those seven measurements occurred on the same day - August 17, 1994. This event was correlated with Tropical Storm Beryl, which made landfall in the southeastern U.S. on August 16th. The state of South Carolina suffered more damage than any other state¹¹.

Overall, turbidity was consistently lower when compared to values from the construction period (see Table 5-12).

Table 5-12. Monitoring Station 564.1 Data Collection Details

Period	Max Depth (m)	Average NTU	Stdev NTU	Max NTU	Count
Pre construction	N/A	N/A	N/A	N/A	N/A
Construction	45	18.5	51.0	476	480
Post construction	44	0.8	2.0	28	890

¹¹ https://en.wikipedia.org/wiki/Tropical Storm Beryl (1994)

5.3.8.1.2 Station 564.0

Pre construction values were measured on average once per month, however, there are several periods without recorded data; the depth-averaged turbidity at Station 564.0 over the dataset was 6.6 NTU (stdev 10) and the maximum was 71 NTU (July 26, 1983). Details of data from Station 564.1 are provided in Table 5-13. Note that Project construction had not yet begun, therefore, these episodes of higher turbidity in the water column were likely due to rainfall events resulting in high inflows from Whitewater River. Elevated values were episodic and specific to the day the measurement was taken (i.e., high NTU values did not carry over to the following measurement). Higher turbidity values were associated with the same six days, listed below (all maximum values were recorded near the bottom of the lake¹²).

- 8/10/1976 (max 50 NTU)
- 3/15/1977 (max 48 NTU)
- 5/16/1978 (max 60 NTU)
- 9/12/1978 (max 38 NTU)
- 7/26/1983 (max 71 NTU)
- 8/27/1985 (max 40 NTU)

During the construction period, the average turbidity was lower than during the pre construction period with an average of 2.9 NTU (stdev 5.2) and a maximum measurement of 57 NTU. All higher NTU readings (within the water column) were associated with the same days and it is noteworthy that all elevated NTU values were at the bottom depth. The elevated turbidity values noted for Station 564.1 (extended periods of time in 1988 and 1990) were not observed at Station 564.0, indicating that elevated turbidity did not extend downstream into Whitewater River cove.

Post construction values at Station 564.0 were lower than pre construction and construction periods (see Table 5-13) with an average of 0.7 NTU (stdev 1.0) and a maximum reading of 14.0 NTU on February 20, 2012. (Note that this elevated turbidity value was from a surface measurement and decreased to <1.0 NTU just below the surface measurement).

¹² Continued decomposition of organic material early in the life of Lake Jocassee also likely contributed to elevated turbidity values

Table 5-13. Monitoring Station 564.0 Data Collection Details

5.3.8.1.3 Station 560.0

Post construction

During the pre construction period, the depth-averaged turbidity was 3.0 NTU (stdev 2.9) and the maximum turbidity value was 19 NTU. Note that half of the elevated turbidity values (i.e., those exceeding 10 NTU) were from a single day on September 12, 1978 (average 13.25 NTU) and includes the maximum reading. During the construction period, there was only one value that exceeded 10 NTU (bottom reading) on February 17, 1988, and during the post construction period, the average NTU was 0.7 (stdev 1.0) with a maximum NTU of 11.6, which was also a bottom reading. Details for monitoring Station 560.0 are included in Table 5-14.

5.3.8.1.4 Surface Turbidity

In addition to values at depth, surface turbidity values were assessed and are provided in Table 5-15 and surface water data tables are included in Appendix B. A boxplot of surface turbidity data over all time periods is provided in Figure 5-6 to show a general summary and distribution of surface turbidity at the three stations. A boxplot is a standardized way of displaying the distribution of a dataset; it provides a five number summary, which includes the minimum, first quartile, median, third quartile, and maximum value of a dataset; the box itself extends from the first to the third quartile and a line is drawn within the box to indicate the median value of the dataset. The whiskers extend to the minimum and maximum numbers in the dataset that are not considered outliers, while outliers are plotted individually above and below the box.

	Lake Jocassee	Turbidity (N	TU)
Station	Minimum	Average	Maximum
560.0	0.00	1.90	17.00
564.0	0.00	1.96	47.00
564.1	0.00	1.61	19.00

Table 5-15. Turbidity in Surface Waters of Lake Jocassee

In freshwater lakes in South Carolina, turbidity is not to exceed 25 NTU provided existing uses are maintained; however, for trout waters, the threshold is not to exceed 10 NTU or 10 percent above natural conditions, provided existing uses are maintained. Over the entire dataset, there were 550 surface samples assessed; a total of 9 samples were above the state standard (i.e., 10 NTU), which accounts for 0.02 percent of the dataset (this also includes data collected during construction). Therefore, surface water turbidity levels in Lake Jocassee fully support the designated use classification (i.e., less than 10 percent criterion excursions).

Figure 5-6. Surface Turbidity in the Whitewater River Arm Over Construction Periods

5.4 Summary Pre construction vs. Post Construction Comparison

Overall, the effect of Bad Creek operations on Lake Jocassee water quality is negligible except for the effects seen at the monitoring station upstream of the submerged weir in Whitewater River cove. Tables of water quality data at the three stations in the Whitewater River cove over the three construction periods are included in Appendix B to show trends in stratification patterns upstream and downstream of the weir and turbidity data are included in Appendix C.

Upstream of the submerged weir, data from monitoring Station 564.1 indicate mixing (from Bad Creek operations), which eliminates all stratification. Temperature and DO values have a uniform profile within the water column at Station 564.1. Immediately downstream of the submerged weir at location 564.0, post Bad Creek operation condition datasets show stratification and trends that follow trends at monitoring locations in other portions of the lake; therefore, based on this desktop review, results indicate that the submerged weir confines mixing to the upstream portion of the Whitewater River cove upstream of the submerged weir and effects of operations are not noted downstream of the weir.

Temperature - Prior to 1991 (pre operations), temperatures averaged throughout the water column in Lake Jocassee averaged between 11.7 and 15.3°C with a standard deviation around 5°C. After 1991, average temperatures in Lake Jocassee averaged between 12.1 and 17.2 °C with a standard deviation around 5°C as shown in Table 5-16. There is little difference between the pre and post operation temperature of Lake Jocassee. The variance in temperature is also reasonably consistent at each station between pre and post operations. As discussed previously, outside of Station 564.1, there are no discernable patterns that would suggest Lake Jocassee temperatures are affected by Bad Creek operations or outside the range of natural conditions and there is no pattern of warming or cooling between time periods (variation between time periods on average is less than one degree); therefore, Project operations have not impacted water temperatures in Lake Jocassee. The notable exception is the average temperature change from pre to post operations at monitoring Station 564.1; this station shows an increase of approximately 3.3°C (see Table 5-16).

Table 5-16. Average and Standard Deviation of Depth-Averaged Temperatures, Pre vs. Post Operations

		Tempera	ture (°C)		
Monitoring	Pre ope	erations	Post op	erations	Difference
Station	Average	Standard Deviation	Average	Standard Deviation	Difference
558.7	12.5	4.9	12.1	4.8	-0.4
558.0	12.9	5.2	13.5	5.4	0.6
559.0	12.5	5.0	12.1	4.9	-0.4
560.0	11.7	4.6	12.3	4.9	0.6
562.0	15.3	5.6	16.0	5.3	0.7
565.4	14.1	5.4	13.1	4.7	-1.0
551.0	13.5	5.8	14.8	7.3	1.3
564.0	12.1	4.7	12.7	4.9	0.6
564.1	13.9	5.6	17.2	5.5	3.3
557.0	11.7	4.5	12.2	4.8	0.5
554.8	14.6	5.5	14.2	5.3	-0.4
556.0	12.8	4.9	13.4	5.2	0.6

Dissolved Oxygen - There is little difference between the pre and post operation conditions of Lake Jocassee. The variance in DO at each station is also reasonably consistent between pre and post operations. As discussed previously, outside of Station 564.1, there are no discernable patterns that would suggest Lake Jocassee DO values are affected by Bad Creek operations or outside the range of natural conditions and there is no pattern of increasing or decreasing DO between time periods (variation between time periods on average is less than 0.5 mg/L); therefore, Project operations have not impacted water temperatures in Lake Jocassee. The notable exception is the average change from pre to post operations at monitoring Station 564.1, which is immediately downstream of the Project I/O structure; this station shows an increase of approximately 1.1 mg/L and the standard deviation dropped from 3.2 to 0.8, indicating there is little variation in DO at that station due to mixing (Table 5-17).

Table 5-17. Average and Standard Deviation of Surface Dissolved Oxygen, Pre vs. Post Operation

Monitoring	Pre ope	rations	Post operations		Difference
Station	Average	Standard Deviation	Average	Standard Deviation	Difference
558.7	6.9	2.4	6.9	1.9	0
558.0	6.5	2.8	7.0	1.8	0.5
559.0	6.5	2.7	6.5	2.2	0
560.0	6.7	2.5	6.4	2.3	-0.3

	≺

		Dissolved O	Oxygen (mg/L)			
Monitoring	Pre operations		Post of	Post operations		
Station	Average	Standard Deviation	Average	Standard Deviation	Difference	
562.0	7.8	2.7	7.9	2.0	0.1	
565.4	7.3	2.9	7.1	2.5	-0.2	
551.0	9.9	1.3	9.6	1.6	-0.3	
564.0	6.4	3.0	6.2	2.6	-0.2	
564.1	7.4	3.2	8.5	0.8	1.1	
557.0	6.8	2.9	6.8	2.3	0	
554.8	7.7	3.1	7.4	2.8	-0.3	
556.0	7.4	2.9	7.3	2.6	-0.1	

Turbidity - Where data are available, NTU values are higher during pre construction periods than during construction and post construction periods. This is true for depth-averaged turbidity (Table 5-18) as well as surface water turbidity (Table 5-19). Pre construction data show episodic elevated turbidity values likely associated with high surface water inflows during storm events from surface runoff. Additionally, turbidity would have been naturally elevated during that time as organic material decomposed in the years following initial reservoir filling. Over the three stations monitored, the highest values of turbidity are associated with monitoring Station 564.1 immediately downstream of the Project (closest to the Whitewater River mouth) during Project construction; however, these elevated turbidity values are not noted at monitoring Station 564.0, indicating that elevated turbidity does not extend downstream into Whitewater River cove.

Additionally, data indicate that elevated turbidity values typically returned to baseline for the following measurement, indicating rapid recovery from elevated values back to normal values (i.e., within one month conservatively, based on sampling frequency). There were several periods of prolonged elevated turbidity values noted at Station 564.1 during the construction period, therefore, these data are assumed to be associated with construction activities. Future construction activities at Bad Creek could increase turbidity in the Whitewater River cove; however, these events would likely be short-lived and based on previous data, recovery in the water column is expected to be rapid.

Table 5-18. Depth-Averaged Turbidity Values (NTU) over Construction Periods

Period	Station 564.1	Station 564.0	Station 560.0
Pre construction	N/A	6.6	3.0
Construction	18.5	2.9	1.5
Post construction	0.8	0.5	0.7

564.1	2.8	3.1	1.0	0.9		

6 Howard Creek

Howard Creek is a high-gradient, third-order, headwater mountain stream. It flows from about 3,200 ft msl to 2,000 ft msl at its confluence with Limber Pole Creek and Lake Jocassee. It is typically less than 30 ft wide and 1.65 ft deep, consists mostly of pools and riffles with steep sections of chutes and waterfalls, and has an average gradient of 8.6 percent (Miller et al. 1997). Howard Creek is a popular recreation stream known for Brook Trout and Rainbow Trout fishing.

6.1 Data Analysis Methods

Pursuant to Article 34 of the original license for the Project (issued to Duke Power Company in 1977) water quality sampling studies in Howard Creek have been carried out, mainly by Clemson University, to assess impacts to Howard Creek associated with construction and operation of the Project.

This section provides an overview of 1993 data presented in Abernathy et al. (1994), which are considered representative of existing (baseline) conditions. While a comparison of water quality between pre and post construction conditions is provided herein (see Section 6.4), water quality data from previous years are documented elsewhere. The body of literature for Howard Creek water quality monitoring is relatively large and there are many notable reports describing water

quality for pre construction, construction, and post construction conditions. References for these germane reports are listed below in Table 6-1.

This report provides a summary of: (1) results from January – December 1993, which represent water quality data for Howard Creek under existing (i.e., operational) conditions and (2) changes observed in water quality between pre construction and post construction data, as presented by Abernathy et al. (1994). While baseflow water quality in Howard Creek and major tributaries was monitored from near Howard Creek's confluence with Lake Jocassee to its headwaters upstream of the Project, this data summary only considers water quality downstream of the Project as upstream waters are not considered impacted by the Project.

6.2 Water Quality Monitoring Stations

As described in Abernathy et al. (1994), water quality parameters were measured at several points along the length of Howard Creek; locations and specific parameters measured were determined in coordination and agreement with FERC, SCDHEC, and the South Carolina Department of Natural Resources (SCDNR) (formerly SC Wildlife and Marine Resources Department). During sampling, agency personnel were kept apprised of water quality monitoring activities and annual reports were submitted (Abernathy et al. 1994). The following five stations (shown on Figure 6-1) were monitored (listed from downstream to upstream) during the study:

- H/1: Between Corbin Creek and Lake Jocassee
- H/2: Between Limber Pole Creek and Corbin Creek
- H/6: Downstream from the Old Schoolhouse Road and an unnamed tributary entering from the east and upstream from Limber Pole Creek
- H/7: Just downstream from Bad Creek

• H/9¹³: Just upstream of Highway 130

Water quality parameters that were measured on a monthly basis include the following: water temperature, DO, pH, specific conductance, total alkalinity, total suspended solids (TSS), turbidity, flow rate/discharge, 5-day biochemical oxygen demand (BOD₅), fecal coliform, and total hardness. Water quality parameters that were measured on a quarterly basis include: ammonia nitrogen, nitrate/nitrite nitrogen, orthophosphate, and total phosphorus. Details on methodology used to collect water quality parameters are included in Abernathy et al. (1994).

¹³ Because Station H/9 is upstream of the Project, it is not considered in this study; however, results are included for completeness.

Note: red star indicates location of USGS 02184475 retired gage on Howard Creek.

Figure 6-1. Howard Creek Monitoring Sites (Abernathy et al. 1994)

6.3 Present-day Water Quality Summary Results

Flow data from the now-retired USGS gage on Howard Creek (USGS 02184475 HOWARD CREEK NEAR JOCASSEE, SC), which drains an area of approximately 2.16 mi², for the available period of record (1989-1996) are provided Table 6-2. The location of the retired gage is shown on Figure 6-1 indicated by a red star symbol. USGS 02184475 is located between H/6 and H/2; data from the retired gage are comparable to flows measured during the Abernathy et al. (1994) study as indicated in Table 6-3 below (from 1993). Water quality information from each

month of the year (1993) at each location is included in Table 6-4 through Table 6-8. A description and numerical range of all water quality parameters is included in Table 6-9.

Notes:

- (1) Discharge values obtained for Stations H/1, H/6, and H/9 are considered to be of good quality and reliable due to cross-sections which are reasonably well suited for discharge measurements.
- (2) Discharge values obtained for Station H/2 are believed to be higher than actual discharge at times due to cross-section conditions which are not well suited for obtaining accurate velocity measurements. Station H/2 has a significant amount of lateral flow. Since early 1981, special care was exercised to minimize the deviations at this Station by noting the angle of flow at each vertical.
- (3) Discharge values obtained for Station H/7 are believed to be higher than actual discharge due to a large proportion of the flow being concentrated in a relatively narrow chute. Special care was exercised to minimize deviations by increasing the number of verticals.

^{*}Instrumental problems with BOD measurement

6.4 Compliance with SCDHEC State Standards

Present day (1993) water quality parameters assessed for Howard Creek and compared against state standards for temperature, DO, pH, and turbidity were all within SCDHEC criteria limits for freshwater (trout) streams.

Since the maximum range of turbidity measured at all three stations in 1993 was consistent with (and even below) those observed during pre construction, baseflow turbidity values under current conditions are considered to be within the trout water turbidity standards set forth by SCDHEC. Post construction DO measurements were greater than the SC trout water standard, therefore DO is also considered to be within state standards for trout waters. Stream standards for trout waters must have a pH of 6.0 to 8.0; mountain streams such as Howard Creek are typically poorly buffered and tend to have low pH values (Abernathy et al. 1994). Low values were recorded in Howard Creek during all phases of sampling and there is a link between pH decreases and prolonged lack of rainfall; however, mean values of pH in 1993 were within the state criteria except for station H/9, which is upstream of the Project and therefore not impacted by the Project. In post construction data, the warmest temperature recorded above and below the Project on Howard Creek was 20.5°C at Station H/2. In pre construction data, water temperatures as high as 21°C were noted, therefore temperatures are consistent and within the range of pre-Project temperatures.¹⁴

The state standard for fecal coliform in waters call for a maximum of 200/100 milliliter (over five consecutive samples during any 30-day period with <10 percent of total samples any 30-day period exceeding 400/100 milliliter. While fecal coliform is not a state standard that would be affected by Project operations, based on these criteria, post construction values for fecal coliform satisfy the trout water standard.

¹⁴ Note that temperature was monitored on a monthly basis in the seepage at the toe of the main dam. The seepage waters appear to have a somewhat constant temperature, but do experience some ponding before they enter Howard Creek. The result tends to be a slight warming of Howard Creek (l-2°C) at Station H/7 during cooler (winter) months and a slight cooling at the same station in warmer (summer) months. In looking at these data along with the pre construction water temperature data tor Howard Creek, there appear to be no negative trends that would be detrimental to the biological community resulting from the construction of the Bad Creek reservoir.

FD3

6.5 Summary Pre construction vs. Post Construction Comparison

Table 6-10 provides water quality parameters for postconstruction (i.e., existing conditions) as well as pre construction (1980-1981) as a comparison, indicating that total suspended solids, turbidity, temperature, DO, pH, BOD₅ and fecal coliform under operational conditions are generally similar and fall well within the range of variation observed during pre construction conditions. Station H/1 is the furthest downstream, Station H/7 is just downstream of the Project, and Station H/9 is the control station (Abernathy et al. 1994). Comparisons between pre construction and post construction water quality data for each monitoring station are included in Figure 6-2 through Figure 6-7.

Figure 6-7. Comparison of Pre and Post Construction pH Values

Overall, Howard Creek, while showing typical annual variations, has remained a high-quality mountain stream with no major changes in the upper portion of the watershed upstream of the Project. Abernathy et al. (1994) notes that even with the major construction of the Project, most baseflow water quality conditions were relatively unchanged during and after construction and post construction water quality conditions are generally similar to pre construction, indicating little or no impact for the parameters studied. Notable changes in water quality that were observed between pre and postconstruction conditions included pH, total alkalinity, total hardness, and specific conductance.

Specific conclusions of the Abernathy et al. (1994) study include the following:

- Howards Creek's baseflow water quality in the postconstruction period is similar to that of pre construction. Differences are within the range of normal seasonal/annual variations with the following exceptions:
 - O During 1991 pH readings were elevated above pre construction and postconstruction, by 1992 the values had returned to near normal, and in 1993 values dropped near or below pre construction, most likely due to lack of rainfall.
 - O Total alkalinity values were elevated above pre construction levels at Station H/7 during 1991 and 1992 and remained elevated through 1993.
 - Total hardness values were elevated above pre construction levels at Station H/7 during 1991 and remained slightly elevated through 1992 and 1993.
 The control Station H/9, however, experienced a drop in mean total hardness during 1993 as compared to the pre construction mean.
 - Specific conductance values were elevated above pre construction levels at Station H/7 during 1991 and 1992 and-although decreasing-remained elevated through 1993.
- The elevated values of total alkalinity, total hardness, and specific conductance, and
 to some extent pH, following construction were likely due to seepage waters through
 the main and west dams coming into contact with grout materials. It is expected that
 these parameters (with the exception of pH) will continue to decline and stabilize
 over time.

6.6 Recent Howard Creek Aquatics Sampling Summary

Results from the initial recovery program suggested Howard Creek had returned to pre construction conditions by 1995. Commencing in 1997 and continuing through 2015, additional

fishery sampling of Howard Creek was implemented to assess whether the recovered state would persist. Sampling was performed at three monitoring stations (H/1, H/6, H/9).

All three survey locations maintained a consistent level of species diversity over the 18-year monitoring study. Generally, species diversity was higher at the downstream location (N=11 species) as compared to the upstream location (N=2 species); this is likely due to species immigration from the reservoir as well as a natural barrier (bedrock slide) found between H/1 and H/6 that hinders fish migration. All three species of trout known to the region (Rainbow Trout, Brown Trout, and Brook Trout) were collected in Howard Creek, but only Rainbow Trout were collected in significant numbers. The condition of Rainbow Trout was similar between the locations over time and was considered healthy. Other common species present in Howard Creek included Bluehead Chub (*Nocomis leptocephalus*), Yellowfin Shiner (*Notropis lutipinnis*), Blackbanded Darter (*Percina nigrofasciata*), Blacknose Dace, and Northern Hog Sucker (*Hypentelium nigricans*).

While water quality wasn't specifically monitored during this 18-year study, the results of the study suggest that Howard Creek has maintained a recovered condition from 1995 to at least 2015 (the last survey period); in the absence of any other known impacts, it is likely Howard Creek currently supports fish populations similar to those found in other southern Appalachian streams, indicating suitable water quality and habitat. Full results of the Howard Creek aquatics study are included in Duke Energy (2016) "Long-term Recovery Monitoring of the Howard Creek Fishery (1997-2015)".

Need for Protection, Mitigation, and Enhancement Measures to Protect Water Quality

Based on the results of this water quality study, and in consideration of results of other data collection efforts in support of the KT relicensing (Duke Energy 2014), there is no need for additional PM&E measures to protect water quality at the Project.

As a condition of the Original License for the Project, and as described in Section 1.6 of the Preapplication Document (Duke Energy 2022), Duke Energy entered into a Memorandum of

Understanding (MOU) with the SCDNR for the long-term management and maintenance of high-quality fishery resources in Lake Keowee, Lake Jocassee, and their tributary streams. The MOU and first 10-Year Work Plan were approved pursuant to Article #32(b)(1) of the Original License for the Project on May 1, 1997. License Article #32(b)(2) covers Lake Jocassee pelagic trout habitat and License Article #34 covers Lake Jocassee water quality. Through this MOU, SCDNR and Duke Energy personnel work cooperatively, and include third parties as necessary, to design and implement data collection and other activities to develop and enhance management strategies for fish in these areas. Activities included in the 10-Year Work Plans are focused on fisheries surveys and inventories, water quality and aquatic habitat evaluations, fish stocking, recreation, and shoreline impacts.

During the New License term, Duke Energy will continue to implement activities established by the MOU, as may be modified in consultation with stakeholders through the relicensing process and will continue to implement PM&E activities established under the KT Project Relicensing Agreement. Duke Energy plans to further consult with SCDHEC and relicensing stakeholders through the Integrated Licensing Process regarding final proposed mitigation and enhancement measures directed at operation of the existing Project and the proposed Bad Creek II Complex to be included in the Final License Application.

It should be noted that in the Environmental Assessment report developed as part of the KT Project relicensing effort in 2014, FERC specifically indicated that (1) existing water quality in the reservoirs and tailwaters (i.e., Lake Jocassee and Lake Keowee) is meeting or exceeding levels consistent with state water quality standards, and is consistent with levels supporting designated uses, and no issues have been raised concerning pH and total dissolved gas; (2) water quality modeling results indicate under the proposed [KT] Project operation, suitable DO levels and water temperatures would exist for the propagation of aquatic life in the Keowee Development water releases; (3) there are no proposed changes in KT Project operation that would alter water quality from existing conditions in the Jocassee Development tailwaters; and (4) the fishery at the KT Project is considered high quality.

This desktop review carried out to support Task 1 of the Water Resources Study is complete and results summarized in this document meet the goals and objectives stated in the RSP to describe

and analyze existing baseline conditions in waters impacted by the Project; data reported herein may serve as a reference for future water quality comparison and assessment.

8 Future Work

Under a separate task of the Water Resources Study (i.e., Task 2), Duke Energy will undertake water quality monitoring (continuous temperature and biweekly DO) at three historic monitoring stations in the Whitewater River arm (stations 564.1, 564.0, 560.0) of Lake Jocassee in June through September 2023 (two-unit powerhouse operation) and 2024 (four-unit powerhouse operation, with all ongoing upgrades complete). Water quality sampling in the Upper Reservoir is infeasible and because the Upper Reservoir directly discharges to Whitewater River cove (with very little other water contribution to the Upper Reservoir), water quality in Whitewater River cove and in particular at Station 564.1, is considered representative of conditions in the Bad Creek Reservoir.

These three locations have been routinely monitored by Duke Energy since the impoundment of Lake Jocassee and historic datasets represent data ranging from 1973 to 2015, depending on the location (provided in Appendix B). The continuous water temperature data will be used to better understand the effectiveness of the existing submerged weir and the effects of existing unit discharge in the Whitewater River arm. Additionally, newly collected water quality data will be compared against historical data and a summary comparison will be provided in the license application.

While Project operations are not expected to impose additional adverse effects on water quality, these baseline water quality data, such as what was compiled and assessed as part of this study, can be used to compare future impacts from construction and operation of the Bad Creek II Complex.

Note that pursuant to the existing MOU between Duke Energy and the SCDNR and subsequent 10-Year Work Plans, Duke Energy continues to collect water quality data in Lake Jocassee to support annual aquatic habitat evaluations. As part of the New License, Duke Energy plans to continue this long-term water quality monitoring program and will develop a Water Quality Monitoring Plan (WQMP) in consultation with agencies focused on the proposed Bad Creek II Complex. The WQMP will include three phases: pre construction, construction, and post

construction of Bad Creek II, including identification of applicable and appropriate threshold values for water quality parameters and monitoring means and methods. The future WQMP will be developed from January – December 2024 for submittal with the Draft License Application (March 2025) pending approval of Bad Creek II Complex construction.

9 Variances from FERC-approved Study Plan

There were no variances from the FERC-approved RSP for this task of the Water Resources Study.

10 Germane Correspondence and Consultation

Germane correspondence will be included with the Water Resources Study Report to be filed with the Initial Study Report in January 2024.

Water Quality Field Procedure

Document number

ESFP-SW-0503

Applies to: Duke Energy – Environmental Science

1.0 Purpose

To obtain representative field data, including but not limited to: water temperature, dissolved oxygen (DO), hydrogen ion activity (pH), specific conductivity, Secchi disk transparency, salinity, turbidity, and photosynthetically active radiation (PAR) as needed to characterize and detect changes in water quality field conditions.

2.0 Forms Referenced in This Procedure

FRM-SW-0502 - Photosynthetically Active Radiation Field Form

3.0 Scope and Frequency

This procedure applies at all times to all field sampling programs in the Environmental Sciences Department that generate water quality data. Water quality monitoring conducted by third parties should be consistent with this procedure. Refer to Site specific study plans or special studies for current year activities.

4.0 Summary of Methods

Water Quality measurement description are detailed in this procedure to ensure collection of accurate, consistent and reliable information. Methods included detail the verification/operation of instrumentation used to quantitatively evaluate physical water conditions and recording of field information to support program objectives.

5.0 Equipment or Apparatus

- 5.1 Meter(s) probe(s), or sensor(s) measuring field parameters including the following but not limited to: temperature, dissolved oxygen (D.O.), pH, conductivity, and turbidity. This also includes any ancillary equipment or hardware required for use of instruments.
- 5.2 Data entry form or datalogger, labels, and pencil or pen.
- 5.3 Secchi disk with graduated line marked at meter and sub-meter increments.
- 5.4 LI-COR® or equivalent underwater spherical quantum sensor, lowering frame, and quantum/radiometer/photometer.
- 5.5 National Institute of Standards and Technology (NIST) traceable thermometer.
- 5.6 Refractometer.
- 5.7 Meter stick.

Rev. 1 (01/2021)	Page 1 of 10
	Rev. 1 (01/2021)

- 5.8 Depth finder/GPS unit.
- 5.9 First aid kit and AED.
- 5.10 Nitrile or latex gloves.
- 5.11 SPOT unit and cell phone.
- 5.12 Polarized safety sunglasses and safety glasses.
- 5.13 Coast Guard approved Personal Flotation Device (PFD) and throwable type IV PFD.
- 5.14 Closed toe non-slip shoes.
- 5.15 Spare batteries or battery charger.
- 5.16 Sunscreen and insect repellant.

6.0 Reagent List

- 6.1 Specific Conductance Standards $(0 50,000 \mu \text{S/cm})$
- 6.2 pH Buffer (4.0, 7.0, and 10.0)
- 6.3 Reagent grade de-ionized water.
- 6.4 Turbidity Standards (Formazin secondary, gel based).
- 6.5 Sodium chloride, reagent grade.
- 6.6 Sodium chloride solution, 10 ppt

Transfer 1.0 ± 0.10 g of sodium chloride to a 100-ml volumetric flask. Add approximately 50 ml of deionized water and dissolve salt. Dilute to volume (100-ml) with de-ionized water.

6.7 Sodium chloride solution, 20 ppt

Transfer 2.0 ± 0.10 g of sodium chloride to a 100-ml volumetric flask. Add approximately 50 ml of deionized water and dissolve salt. Dilute to volume with de-ionized water.

6.8 Sodium chloride solution, 30 ppt

Transfer 3.0 ± 0.10 g of sodium chloride to a 100-ml volumetric flask. Add approximately 50 ml of deionized water and dissolve salt. Dilute to volume with de-ionized water.

7.0 Safety, Limitations, Precautions, and Interferences

7.1 No element of this procedure may supersede the Company's safety standards and policies. Appropriate safety precautions and personal protective equipment (PPE) should be used when handling chemicals. Refer to Safety Data Sheets for specific descriptions of the physical and chemical properties, physical and health hazards, and

precautions for safe handling and use. Formalin is listed as an irritant and potential human carcinogen by the NC Occupational Safety and Health Standards for General Industry. Refer to the Duke Energy Environmental Health and Safety Handbook for guidelines to the proper use of Extremely Hazardous Chemicals.

- 7.2 Field staff are to ensure all pre and post operational instrument checks or calibrations have been performed for the parameters to be measured. These activities should occur prior to (pre) the collection of the first water quality sample and after collection of the final water quality sample (post).
- 7.3 Ensure that equipment found to be out of calibration or functioning improperly is promptly evaluated and the validity of data collected with the instrument since the last calibration is determined in coordination with the Site Lead. Management of this corrective action process will be carried out by instrument managers and field personnel.

7.3.1 Laboratory Supervisor or designee

- 7.3.1.1 Provide water quality instrumentation and equipment that is available to unit personnel for field monitoring or investigative purposes based on calibrations performed according to the frequency given in the instrument calibration procedures section
- 7.3.1.2 Provide a centralized location for field monitoring equipment and ensure "physical" control over equipment.
- 7.3.1.4 For instruments that do not electronically store calibrations internally, attach calibration stickers to instruments and include information as follows: calibration due or expiration date, date calibrated, calibration performed by.
- 7.3.1.5 Ensure that maintenance and repair work are performed as needed and that non-serviceable, uncalibrated, and/or non-functioning equipment is returned to service only after verified repair. Functional instruments are to be stored in centralized equipment storage area.
- 7.3.1.7 Maintain documentation of calibration records (including signature or initials of the persons performing the calibrations), repair, and instrument usage.

7.3.2 ES Personnel

- 7.3.2.1 Use of multiparameter instruments by various manufacturers requires user familiarity. Field staff will review operational manuals prior to usage of water quality instruments. Knowledge of recommended factory or user calibration intervals, specific probe tolerance values, and various maintenance operations are critical in collection of accurate data from this type of instrumentation.
- 7.3.2.2 Perform an operational check or necessary calibration prior to collection of field data.

ESFP-SW-0503	Rev. 1 (01/2021)	Page 3 of 10

- 7.3.2.3 Ensure proper usage, storage and handling of field equipment including transportation to and from laboratory in truck or boat.
- 7.3.2.4 Perform a post operational check after collection of field data.
- 7.3.2.5 Ensure that non-serviceable, uncalibrated, and/or non-functioning equipment is removed from service and flagged and/or tagged with a note indicating that the instrument is not to be used. This will include date, initials, and instrument issue/repair needed.
- 7.3.2.6 Report any damage, malfunction, and/or failure of equipment directly to laboratory supervisor or designee and coordinate to provide prompt evaluation of data collected during field sampling. <u>Do not return</u> malfunctioning instruments to the centralized location.
- 7.4 All standards will be obtained following the approved chemical control procedure.

 Standards for all water quality parameters will be within vendor stated expiration date.

 Expired or used standards will be disposed of properly.
- 7.5 Calibration or calibration check standards expiration date, and lot numbers will be documented based on specific parameters.

8.0 Procedure

- 8.1 Calibration Checks and Calibrations of field equipment (pre and post trip)
 - 8.1.1 Multiparameter Instrument Calibration Check/Calibration
 - NOTE: Pre-sampling calibrations and post calibration checks must be performed each day prior to making field measurements for NPDES compliance monitoring. For South Carolina compliance monitoring calibrations must be conducted at the certified laboratory.
 - 8.1.1.1 Check and Calibration of Dissolved Oxygen (D.O.)
 - 8.1.1.1 Refer to instrument manufacturer calibration instructions (In-situ, YSI, or Hydrolab) for dissolved oxygen. At a minimum, either 100 % saturated air or water calibrations will be performed based on manufacturer instructions for specific instrumentation.
 - 8.1.1.2 Determination of accuracy and or need for calibration will be conducted by placing the DO probe in 100% saturated air or 100% saturated water.
 - 8.1.1.1.3 Document the barometric pressure and instrument temperature. If check or calibration occurs at altitude, barometric pressure-corrected values should be used to correct for elevation above sea level.
 - 8.1.1.1.4 Document instrument conductivity for calibration/checks if calculating known dissolved oxygen concentration for saturated water.

ESFP-SW-0503	Rev. 1 (01/2021)	Page 4 of 10
--------------	------------------	--------------

NOTE: An excel spreadsheet is utilized to calculate predicted dissolved oxygen concentrations (mg/l) in water based on USGS DO solubility reference tables . The spreadsheet will be checked annually for accuracy against USGS values.

8.1.1.1.5

AIR CALIBRATION – Ensure the dissolved oxygen probe is dry by carefully blotting the measuring surface with a lint free wipe. Place the probe in the calibration cup with sufficient moisture to enable air saturation.

WATER CALIBRATION – Ensure the dissolved oxygen and temperature sensors are fully immersed in airsaturated water.

- 8.1.1.1.6 Allow the instrument to equilibrate until the dissolved oxygen % saturation is stable based on manufacturer specifications.
- 8.1.1.7 For non-NPDES compliance related monitoring: if the % saturation is between 98.0% and 102.0%, no calibration is needed. Document the % saturation reading from the instrument and move to the next parameter to be checked.
- 8.1.1.1.8 For NPDES compliance related monitoring OR If the % saturation is outside of 98.0% 102.0% for non-NPDES compliance related monitoring: follow the calibration procedure in the instrumentation manual and document the new % saturation and calibration values accordingly (8.2.4).
- 8.1.1.1.9 For South Carolina NPDES compliance related monitoring, a laboratory control standard (LCS) and an LCS duplicate (LCSD) must be analyzed to verify calibration prior to field analysis. The LCS and LCSD must be within 98.0% 102.0% of the calibrated value

8.1.1.2 Check and Calibration of pH

- 8.1.1.2.1 Refer to instrument manufacturer calibration procedures (In-situ, YSI, or Hydrolab) for pH. Initial daily calibrations are required for all NPDES permit required monitoring.
- 8.1.1.2.2 Inspect the status of the pH probe. If the glass bulb at the end of the probe is cloudy or damaged, or if the probe body is cracked or broken, replace the probe.
- 8.1.1.2.3 Three-point checks or calibrations are to be performed using traceable pH standards (values 4.0, 7.0, 10.0) according to manufacturer instructions.

- 8.1.1.2.4 Prior to recording instrument values for individual check or calibration reference standards, probes should be rinsed with deionized water, then triple rinsed with fresh respective pH standard 4.0, 7.0, or 10.0.
- 8.1.1.2.5 Fresh standards should be used to obtain values for calibration. Record values after pH readings have stabilized.
- 8.1.1.2.6 Calibration is required if NPDES permit required monitoring is to be performed or if measured pH readings deviate from the standard by more than 0.2 pH units for other monitoring. Follow calibration instructions in the instrumentation manual and document post-calibration pH values accordingly (8.2.4).
- 8.1.1.2.7 Calibration must be verified with a known traceable 7.0 pH reference standard prior to collection of field data. Standard verification results must be with 0.1 pH units of the known standard value to be accepted. If standard values are outside this range corrective action should be taken to identify instrument or calibration process deficiencies.
- 8.1.1.2.8 A calibration check must be conducted after every ten samples using a traceable pH standard when NPDES sampling is being performed.
- 8.1.1.2.9 Post check verification values are recorded after daily sampling activities are conducted. Values for 4.0, 7.0, and 10.0 standards are to be within 0.1 pH units for NPDES permit required monitoring, or 0.2 pH units for other monitoring.
- 8.1.1.3 Check and Calibration of Specific Conductivity
 - 8.1.1.3.1 Refer to instrument manufacturer calibration procedures for conductivity (In-situ, YSI, or Hydrolab).
 - 8.1.1.3.2 Inspect the operational condition of the conductivity probe (i.e cracks, film, fouling etc.).
 - 8.1.1.3.3 Perform a zero check in air. Rinse the conductivity probe with de-lonized water and blot the probe dry with lint free paper. Value should read 0.0 µS/cm. Record the specific conductance value in the appropriate format.
 - 8.1.1.3.4 Triple rinse the conductivity probe with fresh traceable reference standard (typically 150 µS/cm for inland waters).
 - 8.1.1.3.5 Place the probe in the calibration cup containing fresh standard. Record the specific conductance value in the

ESFP-SW-0503 Rev. 1 (01/2021) Page 6 of 10

appropriate format.

- 8.1.1.3.6 Calibration is required for NPDES permit required monitoring and if the at check, the measured specific conductance (µS/cm) deviates from the standard by more than 10%. Follow the calibration procedure in the instrument manual and document post-calibration values in the appropriate format (8.2.4).
- 8.1.1.4 Check of Non-NIST Digital Thermistors for Temperature (annually, at a minimum)
 - 8.1.1.4.1 Inspect the operational condition of the temperature probe.
 - 8.1.1.4.2 Immerse the temperature probe into a bucket of water alongside a NIST certified temperature probe and allow for equilibration. Record the temperature readings from both instruments in the appropriate format (8.2.4).
 - 8.1.1.4.3 If the temperature value deviates from the NIST certified probe by more than 0.2°C, condition of the probe should be checked prior to collection of field data. Differences of 0.5 °C or greater require replacement of the temperature probe.
- 8.1.2 Calibration Check/Calibration of Turbidity
 - 8.1.2.1 Follow procedure ESFP-SW-0500.
- 8.1.3 Calibration Check of Refractometers (Salinity)
 - 8.1.3.1 Ensure the refractometer is clean and no scratches are present on the lenses.
 - 8.1.3.2 Triple rinse the refractometer with De-lonized water and zero the instrument if necessary.
 - 8.1.3.3 Triple rinse the refractometer with salinity standard solution (10ppt) and place a small amount of solution on the sensor and record the salinity values in the appropriate format.
 - 8.1.3.4 Triple rinse the refractometer with salinity standard solution (20ppt) and place a small amount of solution on the sensor and record the salinity values in the appropriate format.
 - 8.1.3.5 Triple rinse the refractometer with salinity standard solution (30ppt) and place a small amount of solution on the sensor and record the salinity values in the appropriate format.
 - 8.1.3.6 Discard the refractometer if the salinity values deviate from the standards by more than 10%.

- 8.1.4 Calibration Check of Photosynthetically Active Radiation (PAR)
 - 8.1.4.1 Inspect the functionality and integrity of the sampling device.
 - 8.1.4.2 An annual calibration is conducted by the manufacturer. Calibration verification information is stored electronically for reference.
- 8.1.5 Calibration Check of Secchi depth cable
 - 8.1.5.1 Validate the distance markings on the depth cable annually and record. Verify markings are clear and discernable prior to each field usage. Validation information is stored electronically for reference.
- 8.1.6 Calibration Check of NIST thermometer
 - 8.1.6.1 Inspect the temperature probe for damage and sufficient battery life for field usage.
 - 8.1.6.2 Calibration of NIST thermometers performed annually by a third party. Calibration verification information is stored electronically for reference.
- 8.2 Collection of water quality data
 - 8.2.1 Record information specific to various programs or studies including but not limited to: site location code, date, sampler identification, station, weather conditions, instrument number, time of sample collection (military format). All information is recorded in an appropriate format enabling consistent and accurate tracking and verification of samples during and after collection (electronic format preferred).
 - 8.2.2 To record water quality parameter values such as D.O., pH, specific conductivity, or temperature, lower the multiparameter meter to surface depth to collect data. Allow time for the instrument to equilibrate and record measurements. Single point surface measurements collected in flowing water should be collected at this depth. Vertical profile water quality data should be collected at intervals described in specific study plans.
 - 8.2.3 To record PAR data the spherical quantum sensor and lowering frame are held just above the surface of the water on the sun-lit side of the boat or stream for a measurement of the amount of incident (I_o) light that is reaching the water surface. Photosynthetically active radiation is measured based on site specific study plan or site depth. Data are recorded on the Photosynthetically Active Radiation Field Form (FRM-SW-0502).
 - 8.2.4 Equilibration time is allowed at each depth. Values recorded are as follows:

Temperature to the nearest 0.1 (°C) D.O. to the nearest 0.1 (mg/L)

pH to the nearest 0.1 (standard unit)
Conductivity to the nearest 1.0 (μmho/cm)

Salinity to the nearest 0.1 (ppt)

PAR to the nearest $0.01 \, (\mu \text{E/sec/m}^2)$

Turbidity to the nearest 0.05 @ 0-1 (NTU) to the nearest 0.1 @ 1-10 (NTU) to the nearest 1.0 @ 10-40 (NTU) to the nearest 5.0 @ 40-100 (NTU) to the nearest 10 @ 100-400 (NTU) to the nearest 50 @ 400-1000 (NTU) to the nearest 100 @ >1000 (NTU)

- 8.2.5 The bottom sample depth is recorded by rounding to the nearest meter.
- 8.2.6 Secchi disk depth is read at each reservoir station or as required by the current monitoring program. Record Secchi disk depth to the nearest 0.1 m.

 Measurements should be an average of two readings first when the disk disappears and the second when the disk reappears as it is being raised. In addition, measurements should be recorded on the shaded (and if possible, leeward) side of the boat without the use of sunglasses.
- 8.2.7 Procedure discrepancies occurring in the field should be noted on the data sheet or in the comments section of data logging device.

9.0 Calculations

N/A

10.0 Results

Collected field data may be recorded electronically (preferred) or in field notebooks. Hard copy data will be transferred to a digital format following the appropriate QA protocol (see section 13.4). Electronic field data will be loaded to an electronic data storage system for end user analysis.

11.0 Definitions

Calibration Check – Comparison of measured values to known traceable standard.

Calibration – An adjustment made to the instrumentation to bring measured values of known traceable standards within approved/acceptable tolerances.

Operation Check – Ensuring an instrument has power and that measured values are stable without comparing it to known standards.

Multiparameter Instrument – An instrument capable of measuring multiple water quality parameters simultaneously by way of multiple specific probes.

Water Quality – A measured quantitative value generated by an instrument or device that is representative of a physical water condition (water temperature, DO, pH, conductivity, Secchi disk transparency depth, salinity, and PAR)

Surface – An area of the water column beginning at the air water interface and extending down to 0.30 meters in depth.

13.0 Quality Control

- 13.1 Qualified personnel are responsible for briefing personnel on sample collection, study objectives, and sampling locations.
- 13.2 All project area stations will be sampled on the same day if possible.
- 13.3 If data are collected in field notebooks and transferred to a digital format, the newly created digital file must be verified by a second party to ensure the data has been transcribed accurately.
- 13.4 South Carolina NPDES specific: for samples not analyzed *in-situ*, a sample duplicate must be analyzed with each batch of 20 or fewer samples and must recover within the laboratory's acceptance criteria (± 0.2 SU of the first sample aliquot for pH, 10% of known standard value for specific conductivity) when conducting NPDES sampling in South Carolina.13.5 South Carolina NPDES specific: personnel conducting water quality

ESFP-SW-0503	Rev. 1 (01/2021)	Page 10 of 10

field collection in South Carolina waters for NPDES related monitoring will participate in initial demonstration of capability (IDOC), and continuing demonstration of capability (CDOC) for variables included as certified field laboratory parameters.

13.6 NPDES Specific Conditions

Parameter	North Carolina Specific Methods	South Carolina Specific Methods	Standard	Acceptance Criteria ¹
Temperature	SM 2550 B-2010 USGS Method 1975	SM 2550 B-2010	NIST-traceable device	Annual temperature accuracy verification: ±0.2 °C of NIST device temperature
Dissolved Oxygen	ASTM 0888-09 (C) ASTM 0888-05 HACH 10360 SM 4500-O C-2011 SM 4500-O G-2011	ASTM 0888-09 (C)	Water-saturated air, or air- saturated water	LCS/LCSD within 98 - 102 % of theoretical saturation concentration
Specific Conductance	SM 2510 B-2011 SW-846 9050A	SM 2510 B-2011	NIST-traceable KCI standard	±10% of standard LFB or CCV value
рН	SM 4500-H B-2011 SW-846 9040 C SW-846 9045 D	SM 4500-H B-2011	NIST-traceable buffers	±0.1 pH units of buffer value for calibration or check, ±0.2 pH units for duplicate

- 13.7 South Carolina NPDES specific: for specific conductivity samples not analyzed *in-situ*, a laboratory control sample (LCS) must be analyzed after every 10 samples and at the end of each analysis batch.
- 13.8 Specific conductivity instrument automatic temperature compensation will be verified before initial use and annually for equipment used to perform NPDES monitoring. Verification will be performed by analyzing standards which bracket observed temperature conditions where samples are to be collected, and a third temperature of 25° C. All standards measured at, above, or below 25° C must be within 10% of the true value of the standard. Equipment not meeting these criteria will be taken out of service for corrective action.
- 13.9 Initial and annual temperature verification will be performed on non-NIST thermometers. Comparison of a minimum of two temperature conditions which bracket field sample conditions will be performed for any instrument involved in water quality data collection. All temperatures measured must be within ± 0.2 °C of a certified NIST device. Equipment not meeting criteria will be taken out of service for corrective action

¹ The calibration acceptance criteria shown are based on NC and SC lab certification requirements and may in certain cases be modified by study plan-specific criteria, but only for studies that **are not** NPDES compliance-related. All compliance data must meet the criteria in this table. Consult applicable study plans for further details.

Procedure Number: ESFP-SW-0504

Procedure Title: Water Chemistry Field Sample Collection

Applicability: Applies to Duke Energy, Environmental Science Field Programs

Originator: Environmental Science Group

Approval: Zachary Hall – Director Environmental Science

Signature:

Approval Date: 01/01/2020

Effective Date: 01/01/2020

Summary of Changes

Revision Number	Date Revised/Reviewed	Summary of Changes (Include Page Number)	Revision By
0	01/01/2020	New Procedure	J.C. Green

Water Chemistry Sampling Procedure

Document number

ESFP-SW-0504

Applies to: Duke Energy – Environmental Science

1.0 Purpose

To provide representative, viable water chemistry samples as needed to allow for various characterizations of waterbodies associated.

2.0 Forms Referenced in This Procedure

Sample chain of custody forms for various programs.

3.0 Scope and Frequency

This procedure applies to field sampling programs in the Environmental Sciences Department that generate water chemistry data. Water chemistry sampling conducted by third parties should be consistent with this procedure. Refer to location specific study plans for current year.

4.0 Summary of Methods

Water samples are collected in an appropriate manner depending on analyte requirements. Samples are placed in labeled containers, preserved according to current analytical methodology, and sent to a laboratory within holding times for various analysis. A sample chain of custody is generated and maintained as required.

5.0 Equipment or Apparatus

- 5.1 Cooler, and ice.
- 5.2 Sample bottles containing appropriate preservatives as required for analysis.
- 5.3 Nonmetallic, subsurface water bottle sampler.
- 5.4 Data entry form or labels, and pencil or pen.
- 5.5 Depth finder/GPS unit.
- 5.6 Peristaltic pump with power supply.
- 5.7 Individually bagged pump tubing (Tygon® or equivalent for pump, HDPE for collection segment).
- 5.8 High capacity, 0.45 µm cartridge filters (meets analytical requirements).
- 5.9 Powder-free Nitrile, polyethylene, vinyl or latex disposable gloves.
- 5.10 First aid kit and AED.

ECED CIVI OFOA	D 0 (04/0000)	Dania 4 af 40
ESFP-SW-0504	Rev. 0 (01/2020)	Page 1 of 12

- 5.11 SPOT unit and cell phone.
- 5.12 Polarized safety sunglasses and safety glasses.
- 5.13 Coast Guard approved Personal Flotation Device (PFD) and throwable type IV PFD.
- 5.14 Closed toe non-slip shoes.
- 5.15 Spare batteries or battery charger.
- 5.16 Wide range (0-14) pH test strips.
- 5.17 Nonmetallic bridge sampling basket.
- 5.18 Spare sample bottle kit.
- 5.19 Field Computer and portable media storage.

6.0 Reagent List

- 6.1 De-ionized reagent grade water.
- 6.2 Laboratory grade detergent (Liquinox® or equivalent).
- 6.3 Preservatives as defined in Figure 1.

7.0 Safety, Limitations, Precautions, and Interferences

- 7.1 No element of this procedure may supersede the Company's safety standards and policies. Appropriate safety precautions and personal protective equipment (PPE) should be used when handling chemicals. Refer to Safety Data Sheets for specific descriptions of the physical and chemical properties, physical and health hazards, and precautions for safe handling and use. Formalin is listed as an irritant and potential human carcinogen by the NC Occupational Safety and Health Standards for General Industry. Refer to the Duke Energy Environmental Health and Safety Handbook for guidelines to the proper use of Extremely Hazardous Chemicals.
- 7.2 Surface samples are collected just below the surface to avoid collecting surface film.
- 7.3 If a preserved sample is spilled or the bottle is overfilled, the sample must be tested for appropriate pH level and discarded/ recollected if samples are not adequately preserved. pH testing is done by pouring a small amount of sample over the strip, not by inserting the strip into the sample container.
- 7.4 Samples should be collected, handled, and transferred to the minimum extent possible to reduce contamination. **Direct dip method** is preferred when possible to minimize the contact of sample from multiple containers.
- 7.5 Samples collection time should be recorded as identical to water quality condition collection time unless times are outside of 15 minutes.
- 7.6 Sample chain of custody sheets are maintained, and all pertinent information will be filled out accurately and completely. Store all water chemistry samples using

ECED CM OFOA	D 0 (04/0000)	D 0 -f 10	
ESFP-SW-0504	Rev. 0 (01/2020)	Page 2 of 12	

appropriate preservation techniques, and in a manner that maintains secure custody and relinquish to the laboratory as soon as possible to avoid exceeding sample holding times.

7.7 Location characteristics should be evaluated prior to any sample collection in order to prevent sample contamination due to various factors. Special consideration should be given to Low Level Mercury and other low-level metals sample collection. See procedure ESFP-SW-0502 for details on this specific process prior to sampling.

Examples of unfavorable conditions include but are not limited to: material spills nearby, leaking fuel/oil from boat motors, or pesticide/herbicide spraying near the sampling location. If samples are collected during atypical conditions, details should be included on field records and chain of custody to provide clarification on analytical results if needed.

7.8 Prior to sampling trip ensure that the appropriate number and type of sample containers are included in field gear. This includes appropriate labels for location/analyte identification and preservatives.

8.0 Procedure

- 8.1 Navigate to the sampling location. Using GPS or other landmark, to verify location.
- 8.2 Sampling personnel will put on new gloves prior to sample collection or handling of sampling equipment. If gloves are contaminated during use they will be replaced with a new pair. New gloves will be used at each individual sampling location.
- 8.3 Sampling locations should be visited in a manner that initiates the sampling day at the least contaminated location and progresses towards the most potentially contaminated location when possible. Sampling of spatial composite locations is to be performed in the same manner from least to most known contaminated areas.
- 8.4 Label sample container with the sample number, location code, station code, date, and depth using waterproof marking pen. If sample bottles are pre-labeled, verify location information prior to collection.
- 8.5 Non-preserved sample containers and sampling devices will be rinsed a minimum of two times with site water prior to filling the sample container. Bottles containing preservatives must not be rinsed prior to filling. Care must be taken not to overfill the bottle as preservative may be lost or diluted.
 - 8.2.1 If direct dip method is used to collect grab samples, always collect the sample with the container opening facing upstream to avoid contamination from gloves. If no current is present, use a forward sweeping motion to avoid backflow of water from around the sample bottle. Sample containers should be immersed under the air water interface during collection of surface samples to avoid surface films or scum.
 - 8.2.2 If a sampling device is used to collect grab samples, the water sample is transferred from the sampler into the sample containers and capped securely. The samples should be sealed as soon as possible with the minimal amount of entrained air to prevent oxidative changes.

- 8.3 Various parameters require specific sample bottles, volume of sample, or sampling technique such as no airspace in the sampling container, or other special considerations to ensure proper preservation. See Figure 1. or refer to analyte methodology for information on specific requirements.
- 8.4 Sampling equipment will be inspected for integrity and potential contaminants prior to field usage. If cleaning is needed a non-phosphorous detergent must be used followed by a thorough rinse using de-ionized reagent grade water. Samplers are to be suspended with accurately marked nylon rope to ensure proper sampling depth. When collecting samples from bridges or roadways, ensure that rope used to suspend the sampler does not contact railings or other structures which could result in contamination.
 - 8.4.1 Van Dorn style samplers are typically used to collect discrete depth grab samples from a specific depth in the water column. Refer to user manual for proper use and sample collection techniques. Bottom samples are collected ~ 0.5 m from bottom. If silt or sediment appears in sample or if sampling gear does not properly seal, sample must be discarded and recollected.
 - 8.4.2 Integrated Depth Sampler (IDS) may be used to collect both discrete grab and spatial composite samples of the water. When used for collection of spatial photic zone composite sampling, the IDS is lowered through the water column at a consistent rate to a depth equal to twice the secchi depth, and returned to the surface at the same rate. If the sampler fills prior to being returned to the surface, the sampler must be emptied and the photic zone resampled to ensure proper collection.
- 8.5 Samples requiring In-Field sample filtration will be filtered immediately on location as conditions allow. Secondary collection devices may be used to obtain designated depth samples when filtration is required.
 - 8.5.1 Battery powered peristaltic pumps are preferred for field filtered samples. If location conditions do not allow for immediate on-site field filtration, filtration may occur at a more appropriate location within 15 minutes of sample collection.
 - 8.5.2 A length of new, unused pump tubing should be placed in the pump head and secured to a longer length of HDPE sample tubing to be placed at the designated sampling depth.
 - 8.5.3 Prior to filling sample bottles, pump tubing and filter (if needed) will be flushed for a minimum 20 seconds.
 - 8.5.4 When filtered samples are being collected, attach a new unused $0.45~\mu m$ cartridge filter to the outlet end of the pump tubing. Turn the pump on and orient the outlet end of the filter (directional) up to allow air to be purged. After flushing as described in step 8.5.3, fill sample bottles according to steps 8.2.1 and 8.2.2.
 - 8.5.5 After all samples have been collected at a location, discard the tubing and filter. New tubing and filters are to be used at each location, and should remain bagged until use.
- 8.6 Samples require appropriate temperature and chemical preservation, and tracking.

FOFD OW OFOA	D 0 (04/0000)	D 4 . 540	
ESFP-SW-0504	Rev. 0 (01/2020)	Page 4 of 12	

- 8.6.1 Samples are placed into location specific sealed bags and immediately stored on ice for transport to the analytical laboratory. If samples are not sent immediately to an analytical lab, they may be stored at a consistent temperature of <6°C.
- 8.6.2 Samples submitted to a laboratory must be accompanied by a chain of custody. A chain of custody will be maintained during sample transfer. Pertinent information will be filled out accurately and completely according to ESFP-AD-0102.

9.0 Calculations

N/A

10.0 Results

Samples collected are sent to an analytical chemistry laboratory for analysis. Results are placed on computer master file to be utilized in annual reports and/or as requested.

11.0 Definitions

Grab sample – Sample collected at a discrete depth and time.

Composite Sample – Sample collected at 2 or more specified locations or times used to represent a spatial or temporal average.

13.0 Quality Control

13.1 Split Samples

Samples representing the same aliquot of the waterbody sampled which are typically used for evaluating sample handling and analytical processes of the recipients of splits samples. When collecting these samples, complete homogenization of samples should occur before samples are dispensed into separate containers.

ESFP-SW-0504	Rev. 0 (01/2020)	Page 5 of 12	

13.2 Duplicate Samples

Duplicate samples are collected as required by study design to evaluate

sample collection and preservation procedures. Duplicate samples are collected in a manner that minimizes changing site conditions while representing all aspects of sample collection.

13.3 Trip Blank

Trip blanks are used to evaluate storage and transport conditions of field samples. These should be treated as normal samples and not be opened in the field. Sample containers are pre-filled with reagent grade water that is transported into the field during sample collection activities, and is stored alongside samples in appropriate storage containers.

13.4 Equipment Blank

Equipment blanks are to be used in evaluation of sampling gear and equipment. Samples are exposed to reagent grade water which is then collected into sample bottles, preserved accordingly and delivered to an analytical lab for analysis.

13.5 Filter Blank

Filter blanks are used to assess the potential for contamination during the sample filtration process. Reagent grade water is processed through a filter in the same manner as a sample and then preserved according to analyte requirements.

13.6 Field Blank

Field Blanks are used to assess site or field conditions experienced during sampling. Samples are exposed to the same conditions as the sample, opened in the field.

13.7 Temperature Blank

Temperature Blanks are vials of water that accompany the samples that will be opened and tested upon arrival at the laboratory to ensure that the temperature of the contents of the sampling shipping container was within the required 6° C \pm 2° .

- 13.8 Site or Trip lead should instruct personnel taking samples in the proper methods, QA sample frequency, and station locations.
- 13.9 Sample holding times vary among analytical procedures. Refer to Figure 1. Or contact analytical laboratory for specific hold time and preservative requirements.

1"P" is for polyethylene; "FP" is fluoropolymer (polytetrafluoroethylene (PTFE); Teflon®), or other fluoropolymer, unless stated otherwise in this Table II; "G" is glass; "PA" is any plastic that is made of a sterilizable material (polypropylene or other autoclavable plastic); "LDPE" is low density polyethylene.

²Except where noted in this Table II and the method for the parameter, preserve each grab sample within 15 minutes of collection. For a composite sample collected with an automated sample (e.g., using a 24-hour composite sample; see 40 CFR 122.21(g)(7)(i) or 40 CFR part 403, appendix E), refrigerate the sample at ≤6 °C during collection unless specified otherwise in this Table II or in the method(s). For a composite sample to be split into separate aliquots for preservation and/or analysis, maintain the sample at ≤6 °C, unless specified otherwise in this Table II or in the method(s), until collection, splitting, and preservation is completed. Add the preservative to the sample container prior to sample collection when the preservative will not compromise the integrity of a grab sample, a composite sample, or aliquot split from a composite sample within 15 minutes of collection. If a composite measurement is required but a composite sample would compromise sample integrity, individual grab samples must be collected at prescribed time intervals (e.g., 4 samples over the course of a day, at 6-hour intervals). Grab samples must be analyzed separately and the concentrations averaged. Alternatively, grab samples may be collected in the field and composited in the laboratory if the compositing procedure produces results equivalent to results produced by arithmetic averaging of results of analysis of individual grab samples. For examples of laboratory compositing procedures, see EPA Method 1664 Rev. A (oil and grease) and the procedures at 40 CFR 141.24(f)(14)(iv) and (v) (volatile organics).

ESFP-SW-0504	Rev. 0 (01/2020)	Page 10 of 12

³When any sample is to be shipped by common carrier or sent via the U.S. Postal Service, it must comply with the Department of Transportation Hazardous Materials Regulations (49 CFR part 172). The person offering such material for transportation is responsible for ensuring such compliance. For the preservation requirement of Table II, the Office of Hazardous Materials, Materials Transportation Bureau, Department of Transportation has determined that the Hazardous Materials Regulations do not apply to the following materials: Hydrochloric acid (HCl) in water solutions at concentrations of 0.04% by weight or less (pH about 1.96 or greater; Nitric acid (HNO₃) in water solutions at concentrations of 0.15% by weight or less (pH about 1.62 or greater); Sulfuric acid (NaOH) in water solutions at concentrations of 0.080% by weight or less (pH about 1.230 or less).

⁴Samples should be analyzed as soon as possible after collection. The times listed are the maximum times that samples may be held before the start of analysis and still be considered valid. Samples may be held for longer periods only if the permittee or monitoring laboratory have data on file to show that, for the specific types of samples under study, the analytes are stable for the longer time, and has received a variance from the Regional ATP Coordinator under §136.3(e). For a grab sample, the holding time begins at the time of collection. For a composite sample collected with an automated sampler (e.g., using a 24-hour composite sampler; see 40 CFR 122.21(q)(7)(i) or 40 CFR part 403, appendix E), the holding time begins at the time of the end of collection of the composite sample. For a set of grab samples composited in the field or laboratory, the holding time begins at the time of collection of the last grab sample in the set. Some samples may not be stable for the maximum time period given in the table. A permittee or monitoring laboratory is obligated to hold the sample for a shorter time if it knows that a shorter time is necessary to maintain sample stability. See §136.3(e) for details. The date and time of collection of an individual grab sample is the date and time at which the sample is collected. For a set of grab samples to be composited, and that are all collected on the same calendar date, the date of collection is the date on which the samples are collected. For a set of grab samples to be composited, and that are collected across two calendar dates, the date of collection is the dates of the two days; e.g., November 14-15. For a composite sample collected automatically on a given date, the date of collection is the date on which the sample is collected. For a composite sample collected automatically, and that is collected across two calendar dates, the date of collection is the dates of the two days; e.g., November 14-15. For static-renewal toxicity tests, each grab or composite sample may also be used to prepare test solutions for renewal at 24 h, 48 h, and/or 72 h after first use, if stored at 0-6 °C, with minimum head space.

⁵ASTM D7365-09a specifies treatment options for samples containing oxidants (e.g., chlorine) for cyanide analyses. Also, Section 9060A of Standard Methods for the Examination of Water and Wastewater (20th and 21st editions) addresses dechlorination procedures for microbiological analyses.

⁶Sampling, preservation and mitigating interferences in water samples for analysis of cyanide are described in ASTM D7365-09a. There may be interferences that are not mitigated by the analytical test methods or D7365-09a. Any technique for removal or suppression of interference may be employed, provided the laboratory demonstrates that it more accurately measures cyanide through quality control measures described in the analytical test method. Any removal or suppression technique not described in D7365-09a or the analytical test method must be documented along with supporting data.

⁷For dissolved metals, filter grab samples within 15 minutes of collection and before adding preservatives. For a composite sample collected with an automated sampler (e.g., using a 24-hour composite sampler; see 40 CFR 122.21(g)(7)(i) or 40 CFR part 403, appendix E), filter the sample within 15 minutes after completion of collection and before adding preservatives. If it is known or suspected that dissolved sample integrity will be compromised during collection of a composite sample collected automatically over time (e.g., by interchange of a metal between dissolved and suspended forms), collect and filter grab samples to be composited (footnote 2) in place of a composite sample collected automatically.

⁸Guidance applies to samples to be analyzed by GC, LC, or GC/MS for specific compounds.

⁹If the sample is not adjusted to pH 2, then the sample must be analyzed within seven days of sampling.

¹⁰The pH adjustment is not required if acrolein will not be measured. Samples for acrolein receiving no pH adjustment must be analyzed within 3 days of sampling.

¹¹When the extractable analytes of concern fall within a single chemical category, the specified preservative and maximum holding times should be observed for optimum safeguard of sample integrity (*i.e.*, use all necessary preservatives and hold for the shortest time listed). When the analytes of concern fall within two or more chemical categories, the sample may be preserved by cooling to ≤6 °C, reducing residual chlorine with 0.008% sodium thiosulfate, storing in the dark, and adjusting the pH to 6-9; samples preserved in this manner may be held for seven days before extraction and for forty days after extraction. Exceptions to this optional preservation and holding time procedure are noted in footnote 5 (regarding the requirement for thiosulfate reduction), and footnotes 12, 13 (regarding the analysis of benzidine).

 12 If 1,2-diphenylhydrazine is likely to be present, adjust the pH of the sample to 4.0 ± 0.2 to prevent rearrangement to benzidine.

ESFP-SW-0504	Rev. 0 (01/2020)	Page 11 of 12

¹³Extracts may be stored up to 30 days at <0 °C.

 14 For the analysis of diphenylnitrosamine, add 0.008% Na₂S₂O₃ and adjust pH to 7-10 with NaOH within 24 hours of sampling.

 15 The pH adjustment may be performed upon receipt at the laboratory and may be omitted if the samples are extracted within 72 hours of collection. For the analysis of aldrin, add 0.008% Na₂S₂O₃.

¹⁶Place sufficient ice with the samples in the shipping container to ensure that ice is still present when the samples arrive at the laboratory. However, even if ice is present when the samples arrive, immediately measure the temperature of the samples and confirm that the preservation temperature maximum has not been exceeded. In the isolated cases where it can be documented that this holding temperature cannot be met, the permittee can be given the option of on-site testing or can request a variance. The request for a variance should include supportive data which show that the toxicity of the effluent samples is not reduced because of the increased holding temperature. Aqueous samples must not be frozen. Hand-delivered samples used on the day of collection do not need to be cooled to 0 to 6 °C prior to test initiation.

¹⁷Samples collected for the determination of trace level mercury (<100 ng/L) using EPA Method 1631 must be collected in tightly-capped fluoropolymer or glass bottles and preserved with BrCl or HCl solution within 48 hours of sample collection. The time to preservation may be extended to 28 days if a sample is oxidized in the sample bottle. A sample collected for dissolved trace level mercury should be filtered in the laboratory within 24 hours of the time of collection. However, if circumstances preclude overnight shipment, the sample should be filtered in a designated clean area in the field in accordance with procedures given in Method 1669. If sample integrity will not be maintained by shipment to and filtration in the laboratory, the sample must be filtered in a designated clean area in the field within the time period necessary to maintain sample integrity. A sample that has been collected for determination of total or dissolved trace level mercury must be analyzed within 90 days of sample collection.

 18 Aqueous samples must be preserved at ≤6 °C, and should not be frozen unless data demonstrating that sample freezing does not adversely impact sample integrity is maintained on file and accepted as valid by the regulatory authority. Also, for purposes of NPDES monitoring, the specification of "≤ °C" is used in place of the "4 °C" and "<4 °C" sample temperature requirements listed in some methods. It is not necessary to measure the sample temperature to three significant figures (1/100th of 1 degree); rather, three significant figures are specified so that rounding down to 6 °C may not be used to meet the ≤6 °C requirement. The preservation temperature does not apply to samples that are analyzed immediately (less than 15 minutes).

¹⁹An aqueous sample may be collected and shipped without acid preservation. However, acid must be added at least 24 hours before analysis to dissolve any metals that adsorb to the container walls. If the sample must be analyzed within 24 hours of collection, add the acid immediately (see footnote 2). Soil and sediment samples do not need to be preserved with acid. The allowances in this footnote supersede the preservation and holding time requirements in the approved metals methods.

²⁰To achieve the 28-day holding time, use the ammonium sulfate buffer solution specified in EPA Method 218.6. The allowance in this footnote supersedes preservation and holding time requirements in the approved hexavalent chromium methods, unless this supersession would compromise the measurement, in which case requirements in the method must be followed.

²¹Holding time is calculated from time of sample collection to elution for samples shipped to the laboratory in bulk and calculated from the time of sample filtration to elution for samples filtered in the field.

²²Sample analysis should begin as soon as possible after receipt; sample incubation must be started no later than 8 hours from time of collection.

²³For fecal coliform samples for sewage sludge (biosolids) only, the holding time is extended to 24 hours for the following sample types using either EPA Method 1680 (LTB-EC) or 1681 (A-1): Class A composted, Class B aerobically digested, and Class B anaerobically digested.

²⁴The immediate filtration requirement in orthophosphate measurement is to assess the dissolved or bio-available form of orthophosphorus (*i.e.*, that which passes through a 0.45-micron filter), hence the requirement to filter the sample immediately upon collection (*i.e.*, within 15 minutes of collection).

1 Introduction and Background

1.1 Project Overview

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir and Lake Jocassee, which is licensed as part of the Keowee-Toxaway Hydroelectric Project (KT Project; FERC Project No. 2503), as the lower reservoir.

The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977 and expiration date of July 31, 2027. The license has been subsequently and substantively amended, with the most recent amendment on August 6, 2018 for authorization to upgrade and rehabilitate the four pump-turbines in the powerhouse and increase the authorized installed and maximum hydraulic capacities for the Project. Duke Energy is pursuing a new license for the Project pursuant to the Commission's Integrated Licensing Process, as described at 18 Code of Federal Regulations (CFR) Part 5. Given the need for additional significant energy storage and renewable energy generation across Duke Energy's service territories over the Project's new 40 to 50-year license term, Duke Energy is proposing to add pumping and generating capacity at the Project. Additional energy storage and generation capacity would be developed by constructing a new power complex (including a new underground powerhouse) adjacent to the existing Bad Creek powerhouse. Therefore, construction of the 1,400-megawatt Bad Creek II Power Complex (Bad Creek II) is an alternative relicensing proposal presently being evaluated by Duke Energy.

In accordance with 18 CFR §5.11 of the Commission's regulations, Duke Energy developed a Revised Study Plan (RSP) for the Project and proposed six studies for Project relicensing. The RSP was filed with the Commission and made available to stakeholders on December 5, 2022. FERC issued the Study Plan Determination on January 4, 2023, which included modifications to one of the six proposed studies (Recreational Resources).

This report details the methodologies and findings from the first (2023) and second (2024) study seasons for Task 2 (Water Quality Monitoring in Whitewater River Arm) of the Water Resources Study. This study was conducted to support the application for a new license for the Project, in accordance with 18 CFR §5.15, as outlined in the RSP.

¹ Duke Energy Carolinas LLC, 164 FERC ¶ 62,066 (2018)

1.2 Study Goals and Objectives

Tasks carried out for the Bad Creek Water Resources Study employ standard methodologies that are consistent with the scope and level of effort described in the RSP filed with the Commission on December 5, 2022. This report was developed in support of the Water Resources Study and is intended to provide sufficient information to support an analysis of the potential Project-related effects on water resources in the Whitewater River Arm of Lake Jocassee.

The goal of Task 2 was to collect and analyze existing water quality data to evaluate the effect of the submerged weir on vertical mixing upstream and downstream of the weir and the influence of the exchange of water on stratification in the Whitewater River Arm. Objectives were met through continuous and biweekly monitoring of water temperature and dissolved oxygen (DO) at three historic monitoring stations in the Whitewater River Arm of Lake Jocassee. Data collection was carried out over two summers (2023 and 2024) from June 1 through September 30 when water temperatures are expected to be warmest and stratification is at its peak.² Data collected in 2023 represented conditions under three-unit operations at the Project while data collected in 2024 represented conditions under four-unit operations.³

Given the absence of water quality data or monitoring in Bad Creek Reservoir, water quality results from this study serve as a representative indication of conditions in the upper reservoir, as water is directly exchanged between the upper reservoir and the Whitewater River arm of Lake Jocasee.⁴ Although Bad Creek II operations are not anticipated to adversely impact water quality, these baseline data can provide a critical benchmark for comparing existing conditions with those observed under future operational phases of the proposed project.

This report encompasses results from both study years and provides a comprehensive assessment of the water quality impacts (temperature and DO) associated with the Project.

1.3 Study Area

The Whitewater River arm (see Figure 1) is in the northwestern portion of Lake Jocassee and receives direct tributary flow from the Whitewater River. Lake Jocasee has a drainage area of approximately 145 square miles

² While the study period for each year is June 1-Sepember 30 as described in the RSP, continuous data are presented through equipment demobilization.

³ Prior to unit upgrades (completed in March 2024), the maximum hydraulic capacity for the Project was 17,234 cubic feet per second (cfs). After the upgrades, the maximum hydraulic capacity is 19,760 cfs.

⁴ Note that water quality monitoring in the Bad Creek Reservoir is not safe (due to rapid, large fluctuations in water level elevation and typically continuous Project operation) nor is it considered meaningful, given the short retention time in the upper reservoir. Due to pumping and generating cycles, retention time is approximately three days if only a single pump-turbine unit is operating. There are no existing water quality data in the upper reservoir; it is used only for Project operations and there is no public access.

(mi²) and roughly 92 miles of shoreline at full pond (1,110 feet (ft) above mean sea level [msl]). Whitewater River arm also directly receives and exchanges water from the Bad Creek Reservoir through the Project's existing inlet/outlet (I/O) structure; the upper reservoir was formed by damming the Bad Creek and the West Bad Creek tributaries of Howard Creek (a tributary of Lake Jocasee). Bad Creek Reservoir has a drainage area of approximately 1.5 mi².

During construction of the original Project, excavated rockfill was transported to the western shore of the Whitewater River arm. From there, it was moved to the lake via barges and used to construct an underwater weir approximately 1,800 ft downstream of the Project's lower reservoir I/O structure (weir midpoint coordinates are 35.0015, -82.991509). The submerged weir, measuring approximately 567 feet in width and 455 feet in length, with a crest elevation of about 1,060 feet above msl, was constructed to mitigate (i.e., minimize) the effects of Project operations on thermal and DO stratification in Lake Jocassee by dissipating the energy of the water discharged from the Project's lower reservoir I/O structure, thereby preserving trout habitat and supporting Lake Jocassee's high quality fishery.

1.4 Water Quality Monitoring Stations

Duke Energy has conducted water quality monitoring throughout Lake Jocassee for over 40 years. To evaluate the influence of the existing submerged weir and Project operations on water temperature and DO stratification in the lake, continuous temperature data and bi-weekly temperature and DO profiles were collected near historical monitoring stations 564.1, 564.0, and 560.0 (Figure 1). The depth at Station 564.1, which is situated between the Project's I/O structure and the submerged weir, is approximately 140 ft. Station 564.0 is located on the downstream side of the submerged weir, upstream of the confluence of the Whitewater River arm and the Thompson River Arm of Lake Jocassee. The depth at this location is approximately 200 ft. Station 560.0 is located in Lake Jocassee downstream of the confluence of the Whitewater River arm and Thompson River arm and is approximately 260 ft deep. Normal maximum pond elevation is 1,110 ft msl and normal minimum pond elevation is 1,080 ft msl.

Detailed water quality data for all historic monitoring stations in Lake Jocassee was provided in the final Water Quality and Summary Standards report (provided in Attachment 1 of Appendix A of the ISR). The historic monitoring station locations differ slightly from the locations monitored during this study; however, the depths and locations are comparable.

Figure 1. Water Quality Monitoring Stations Assessed in the Whitewater River Arm

2 Methods and Instrumentation

Five individual temperature dataloggers were deployed at each of the three monitoring locations during the 2023 field season (June 1 – October 11) and 2024 field season (May 21 – October 8) using an in-Situ VuLink® CI datalogger and telemetry system (VuLink). ⁵ The dataloggers (In-Situ Level Troll 400; range of 60 meters) were attached to a 3/16-inch stainless steel cable and strategically placed at specific depths (noted in Table 1) to continuously monitor changes in thermal and DO stratification throughout the 2023 and 2024 field seasons (Figure 2). The VuLink system features built-in venting and barometric compensation, configurable alarms based on instrument and device parameters, and the ability to log data at intervals from every minute to every seven days. It has a memory capacity of 512 megabytes and can simultaneously connect to eight instruments.

The VuLink device was enclosed within a telescoping aluminum protective cage and attached to a high-visibility buoy. The stainless-steel cables, with the attached dataloggers, were deployed at each monitoring location using a boat-mounted winch and anchored with a weight (Figure 3). The datalogger depths and corresponding Lake Jocassee Pond elevations are detailed in Table 1, noting that these depths and elevations are approximate, as they depend on the fluctuating water levels of Lake Jocassee. Pond elevations recorded during each field season are shown on Figure 4.

Although the VuLink system offers cellular coverage across multiple networks and bands (e.g., LTE Global, Verizon, 2G Quadband), the existing cellular transmission (i.e., cell towers) in the vicinity of the Whitewater River arm is insufficient which required manual data downloads (via boat) during bi-weekly field visits. Data from the VuLink system were downloaded to a secure laptop and discrete vertical profiles of water temperature and DO were measured using Hach[®] Hydrolab DS5 multiprobe⁶ and an In-Situ Troll[®] 500 multiparameter sonde⁷ from the water surface to the reservoir bottom, with bottom depth varying by location. The water column was sampled at approximately 0.3-meter and 1 meter from the surface, then at 2-meter intervals for the remaining profile at all three monitoring stations. Dates of all field visits are included in Table 2.

3 Results

3.1 Study Season 1 (Summer 2023)

3.1.1 Station 564.1

Station 564.1 is immediately downstream of the Project I/O structure and upstream of the submerged weir. From June to early September, epilimnetic water temperatures increased, peaking at 27.7 degrees Celsius (°C) in late July, while hypolimnetic water temperatures peaked in early September at 25.4°C (Figure 5). DO concentrations remained above 7.0 milligrams per liter (mg/L) all at datalogger depths throughout the entire monitoring period (Figure 6).

While there was some minor evidence of thermal stratification between 20 and 40 feet in the earliest part of summer, there was no indication of a stable thermocline, indicating vertical mixing occurred throughout the monitoring period. Vertical mixing is associated with the operation of the Project, which facilitates the direct exchange of water between Bad Creek Reservoir and Lake Jocassee. Vertical mixing at this location is further supported by historical water quality monitoring (Task 1 of the Water Resources Study) and computational fluid dynamics (CFD) modeling conducted for Task 3 of the Water Resources Study.

Continuous temperature data generally indicated a gradual increase in water temperature throughout the summer months, which stabilized in September before experiencing a gradual decline into mid-October (Figure 7). The near surface datalogger recorded greater temperature variability, reflecting diurnal atmospheric temperature fluctuations. This observed variability aligns with the anticipated effects of solar heating and nighttime cooling on surface waters. In contrast, dataloggers positioned at depths between 30 ft and 100 ft recorded relatively stable temperatures, indicative of vertical mixing (due to Project operations) and minimal diurnal temperature variability. This stability displayed effective thermal stratification where deeper waters remain less susceptible to short-term atmospheric temperature changes.

Figure 5. Water Temperature Profiles for Monitoring Station 564.1

Figure 6. Dissolved Oxygen Concentrations for Monitoring Station 564.1

Figure 7. Continuous Water Temperature Profiles for Monitoring Station 564.1

3.1.2 Station 564.0

Station 564.0 is located on the downstream side of the submerged weir, upstream of the confluence of the Whitewater River arm and the Thompson River arm of Lake Jocassee. The recorded surface water temperature exhibited a seasonal trend, characterized by a steady increase throughout the summer months, with a peak temperature of 27.8°C in early September, followed by a gradual decline towards the end of the month (Figure 8). Thermal stratification shows a well-defined thermocline observed at a depth of approximately 100 ft, separating the epilimnion from the hypolimnion. DO concentrations exhibited a consistent decline over the monitoring period from June through September. Surface DO concentrations ranged from 7.3 to 8.8 mg/L, while concentrations at a depth of approximately 200 ft ranged from 0.0 to 2.3 mg/L (Figure 9).

Temperature and DO profiles at Station 564.0 indicate that the presence of the submerged weir minimizes vertical mixing on the downstream side of the weir, as evidenced by the presence of a stable thermocline. This stratification limits the mixing of oxygenated surface waters at depths greater than 100 ft.

Continuous water temperature monitoring data show distinct thermal dynamics at varying depths. Surface water temperatures (at the 3-ft-depth datalogger) reached a maximum of approximately 28.4° C in late July, while temperatures at greater depths (≥ 30 ft) displayed a delayed peak in early September and continued to decline until the end of data collection on October 11, 2023 (Figure 10). As anticipated, the surface water temperatures showed diurnal fluctuations, reflecting the influence of direct solar heating and atmospheric interactions. In contrast, depths at 30, 50, and 70 ft exhibited more stable profiles, with reduced diurnal variability, which are buffered from rapid surface driven temperature changes.

Daily water temperature fluctuations at a depth of 100 ft were larger than fluctuations at depths above 100 ft (Figure 10), likely due to flow circulation patterns immediately downstream of the submerged weir (also shown in the CFD modeling results near this location) and thermal density gradients associated with the thermocline, which were most pronounced at this depth. The submerged weir significantly reduces vertical mixing on the downstream side of the weir which is why thermal and DO stratification is more pronounced compared to Station 564.1 on the upstream side of the weir.

Figure 8. Water Temperature Profiles for Monitoring Station 564.0

Figure 9. Dissolved Oxygen Concentrations for Monitoring Station 564.0

Figure 10. Continuous Water Temperature Profiles for Monitoring Station 564.0

3.1.3 Station 560.0

Thermal and DO profiles at Station 560.0 exhibited stratification patterns similar to those observed at Station 564.0. Throughout the monitoring period, surface water temperatures increased, reaching a peak of 28.1°C, while DO concentrations ranged from 7.8 to 8.9 mg/L (Figure 11 and Figure 12). A thermocline was observed at approximately 100 ft, separating the warmer epilimnion from the cooler hypolimnion.

At Station 560.0, which has a depth of approximately 260 ft, temperatures below the thermocline were approximately 11°C, with DO concentrations ranging from 0.9 to 2.2 mg/L. The deeper and wider channel at this location exhibits less vertical mixing (confirmed by the CFD modeling results) resulting in pronounced thermal and DO stratification.

Continuous water temperature monitoring data are shown on Figure 13. Surface water temperatures reached a maximum of approximately 28.7° C in late August, while temperatures at greater depths (≥ 30 ft) peaked in early September before gradually declining through the end of the study period. Similar to observations at Station 564.0, surface temperatures exhibited diurnal fluctuations.

At 100 ft, water temperature fluctuations were also observed, but the magnitude of the fluctuations were reduced compared to those observed at Station 564.0. This can be attributed to the decreasing influence of flows in the Whitewater River arm as the channel deepens and broadens resulting in a more stable thermal environment.

Pond elevations in Lake Jocassee, as shown on Figure 4, remained within the upper 4 ft of the reservoir's 30-ft operating band from early June through early September. However, during the latter part of the study period, drought conditions resulted in decreased pond elevations (as low as 1,103.3 ft msl, or 6.7 ft below full pond) in early October. Despite this decrease, there was no observable impact on water temperature or DO trends in the recorded data.

Figure 11. Water Temperature Profiles for Monitoring Station 560.0

Figure 12. Dissolved Oxygen Concentrations for Monitoring Station 560.0

Figure 13. Continuous Water Temperature Profiles for Monitoring Station 560

3.2 Study Season 2 (Summer 2024)

3.2.1 Station 564.1

In the early summer months (June – mid-July) of 2024, similar to the previous year, there was some evidence of thermal stratification between 20 and 40 feet. Epilimnetic temperatures peaked at approximately 28.5°C in mid-July, while deeper hypolimnetic waters reached a maximum temperature around 21.0°C (Figure 14). By August, thermal stratification was less evident in the upper water column (likely due to mixing/Project operations) and relatively isothermal conditions persisted through the end of the study period in early October. DO concentrations remained consistently above 6.0 mg/L across all depths, indicating well-oxygenated conditions during the study period (Figure 15).

Continuous temperature monitoring data showed a gradual increase in water temperatures throughout the summer, plateauing in early September before experiencing a gradual decline into mid-October (Figure 16). The surface datalogger (3 ft) recorded greater temperature variability, likely driven by diurnal fluctuations in atmospheric temperatures, corresponding to solar heating during the day and cooling at night. In contrast, temperature loggers positioned at depths of 30 to 100 feet recorded relatively similar thermal conditions, indicative of effective vertical mixing and minimal influence from diurnal atmosphere variability.

The landfall of Hurricane Helene in the Upstate of South Carolina on September 26-27 directly impacted temperatures in the Whitewater River arm (Figure 16); this is discussed in Section 3.2.4.

Figure 14. Water Temperature Profiles for Monitoring Station 564.1

Figure 15. Dissolve Oxygen Concentrations for Monitoring Station 564.1

Figure 16. Continuous Water Temperature Profiles for Monitoring Station 564.1

3.2.2 Station 564.0

The recorded surface water temperature at Station 564.0 exhibited a seasonal progression of stratification, characterized by a thermal increase throughout the summer months with a peak temperature of 28.2°C in mid-July followed by a gradual decline throughout the end of the monitoring period (Figure 17). The thermal stratification at this station was more pronounced compared to Station 564.1, with a distinct thermocline observed at approximately 100 feet, separating the epilimnion and hypolimnion. DO concentrations exhibited a decline over the monitoring period, with epilimnetic concentrations ranging from 7.5 to 8.9 mg/L, while concentrations in the hypolimnion ranged from 0.7 to 7.0 mg/L (Figure 18). This stratification, made evident by the thermocline, indicates the presence of hypoxic conditions at depths greater than 150 feet, where vertical mixing does not occur.

The submerged weir is a significant factor in preventing vertical mixing downstream, allowing for natural thermocline development in Lake Jocassee. The stable thermocline at Station 564.0 was also confirmed through CFD modeling and previous water quality monitoring.

Continuous temperature data (Figure 19) also shows distinct thermal characteristics at the various datalogger depths. The surface water temperatures recorded at the 3-ft-deep logger reached a maximum of approximately 28.2° C in early August, while depths ≥ 30 ft displayed a peak in late August, and declined until the end of the monitoring period. As observed in 2023, surface temperatures exhibited diurnal fluctuations, while depths at 30, 50, 30 and 30, 50, 30 ft showed thermally stable profiles (Figure 17).

Continuous temperature data at 100 ft observed higher variability than at other depths, which can be attributed to the complex flow circulation patterns influenced by the submerged weir. CFD modeling supports the conclusion that the presence of the submerged weir minimizes mixing downstream of the weir allowing natural thermal stratification to develop.

The landfall of Hurricane Helene in the Upstate of South Carolina on September 26-27 impacted temperatures in the Whitewater River arm (see Figure 19); this is discussed in Section 3.2.4.

Figure 17. Water Temperature Profiles for Monitoring Station 564.0

Figure 18. Dissolved Oxygen Concentrations for Monitoring Station 564.0

Figure 19. Continuous Water Temperature Profiles for Monitoring Station 564.0

3.2.3 Station 560.0

The temperature and DO profiles at Station 560.0 displayed similar stratification patterns to those observed at Station 564.0. Surface water temperatures peaked near the end of August at 28.3°C while DO concentrations in the epilimnion ranged from 6.3 to 8.9 mg/L to (Figure 20 and Figure 21). Also similar to Station 564.0, a defined thermocline was present at approximately 100 feet.

Temperatures recorded in the hypolimnion ranged from 11.0 to 17.6 °C, while DO concentrations ranged from 3.9 to 6.3 mg/L. The greater depth and wider channel at this station likely contributed to the observed stratification by promoting a stable thermal gradient inhibiting thermal mixing.

Continuous water temperature monitoring further illustrated the seasonal thermal dynamics observed at this station. Surface water temperatures peaked at approximately 28.7°C in early August, while temperatures at greater depths than 30 ft peaked in 25.8°C in early September, followed by a gradual decline toward the end of the monitoring period. Diurnal fluctuations in surface water temperatures were observed, as expected, reflecting diel cycles of solar heating and radiative cooling. Similar to Station 564.0, water temperature fluctuations at the 100-ft depth were also evident, likely influenced by complex circulation patters and thermal density gradients downstream of the weir as discussed above. This effect, supported by CFD modeling, highlights the significant role of the weir, as it dissipates effects of Project operations (Figure 22).

The landfall of Hurricane Helene in the Upstate of South Carolina on September 26-27 impacted temperatures in the Whitewater River arm; this is discussed in Section 3.2.4.

Figure 20. Water Temperature Profiles for Monitoring Station 560.0

Figure 21. Dissolved Oxygen Concentrations for Monitoring Station 560.0

Figure 22. Continuous Water Temperature Profiles for Monitoring Station 560.0

3.2.4 Hurricane Helene

On September 23, 2024, the National Oceanic and Atmospheric Administration classified a developing storm system near the Cayman Islands as a tropical storm, projected to impact northwestern Florida. By September 26, the tropical storm intensified into a Category 4 Hurricane with sustained wind speeds reaching 140 miles per hour (mph) making landfall with a 15-ft storm surge near Tallahassee, Florida. Over the next 24 hours, Hurricane Helene headed northwest affecting Georgia, South Carolina, North Carolina, Tennessee, and Virginia, with a storm radius extending over 300 miles (NOAA 2024).8

During this event, the Jocassee Gorges watershed experienced up to 18 inches of precipitation over a three-day period. Rainfall at the Project totaled 15.89 inches (Alan Stuart, personal communication). This extreme precipitation event is considered a 1,000-year flood, a hydrological occurrent with a 0.1 percent annual probability (NOAA 2024). Continuous temperature data in Lake Jocassee for the day before the event and for several days after the event are shown below on Figure 23 (Station 564.1), Figure 24 (Station 564.0), and Figure 25 (Station 560.0).

Continuous temperature monitoring at Station 564.1 (Figure 23) showed a sudden decline in water temperatures (except for surface temperatures) and temperatures reached approximately 21°C at the three deepest dataloggers. This pattern indicates a substantial influx of cooler water from the Whitewater River into Lake Jocassee consistent with the timing of the hurricane event. Temperatures recovered (i.e., became mixed) after the initial decline, with the lower datalogger (100-ft) taking longest to recover to pre-hurricane temperatures. Figure 23 also shows Lake Jocassee elevations; Duke Energy drew the lake down to 1,099 ft msl on September 26 in preparation for the predicted storm.

As shown on Figure 24 and Figure 25, the combined effects of storm-driven wind stress, colder inflows, and decreasing air temperatures promoted vertical mixing, facilitating the descent of cooler, denser epilimnetic water. This, in turn, caused an upwelling of hypolimnetic water, leading to a temporary downward shift in the thermocline, which was observed at the deepest dataloggers for both stations downstream of the weir.

The rainfall from Hurricane Helene and impacts from this event on water temperatures and mixing in Whitewater River arm, while significant, were temporary and not typical.

4 Summary

Duke Energy collected continuous water temperature data and periodic DO concentration data (bi-weekly) from locations near three historic monitoring stations to determine current-day representative (i.e., baseline) water quality information. Data collected in 2023 represented conditions under three-unit operations and data collected in 2024 represented conditions under fully upgraded four-unit operations at the Project. There is no noticeable difference in the water quality datasets due to increased pumping or generation. Results from both years indicate water upstream of the submerged weir is, as expected, well-mixed and does not stratify, or is weakly stratified for a short period of time in early summer in the upper water column. Data from monitoring locations downstream of the weir reveal stratification under all pumping and generation scenarios, indicating the weir is functioning as it was designed and helps to dissipate energy from the I/O structure. This preservation of stratification downstream of the weir is also supported by historical water quality monitoring and by CFD model results under current project conditions as well as Bad Creek II conditions, which will have near double the flows generated from the combined powerhouses.

Due to the relatively small surface area, high degree of mixing, and short residence time of water in the Bad Creek Reservoir, warming impacts due to solar radiation in the upper reservoir are limited, therefore, conditions in the Whitewater River arm are reflective of conditions in the upper reservoir.

Duke Energy plans to develop a Water Quality Monitoring Plan in consultation with agencies and other relicensing stakeholders focused on effects of construction and operation of Bad Creek II on water quality in the Whitewater River arm. The Water Quality Monitoring Plan is currently under development and will be submitted with the Draft License Application (March 2025).

1 Project Introduction and Background

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir (Upper Reservoir) and Lake Jocassee, which is licensed as part of the Keowee-Toxaway (KT) Hydroelectric Project (FERC Project No. 2503), as the lower reservoir.

The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977 and expiration date of July 31, 2027. The license has been subsequently and substantively amended, with the most recent amendment on August 6, 2018 for authorization to upgrade and rehabilitate the four pump-turbines in the powerhouse and increase the Authorized Installed and Maximum Hydraulic capacities for the Project. Duke Energy is pursuing a new license for the Project pursuant to the Commission's Integrated Licensing Process, as described at 18 Code of Federal Regulations (CFR) Part 5.

In accordance with 18 CFR §5.11 of the Commission's regulations, Duke Energy developed a Revised Study Plan (RSP) for the Project and proposed six studies for Project relicensing. The RSP was filed with the Commission and made available to stakeholders on December 5, 2022. FERC issued the Study Plan Determination on January 4, 2023, which included modifications to one of the six proposed studies (Recreational Resources Study).

This report includes the methods and results of Task 3 (Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse) of the Water Resources Study. The Water Resources Study is ongoing in support of preparing an application for a new license for the Project in accordance with 18 CFR §5.15, as provided in the RSP.

¹ Duke Energy Carolinas LLC, 164 FERC ¶ 62,066 (2018)

2 Study Goals and Objectives

Tasks carried out for the Bad Creek Water Resources Study employ standard methodologies that are consistent with the scope and level of effort described in the RSP. This report is intended to provide sufficient information to support an analysis of the potential Project-related effects on water resources with clear nexus to the Project.

The main objectives of this task include:

- Use a two-dimensional (2-D) hydrologic model to determine the downstream extent of potential effects (i.e., mixing) from an additional powerhouse in the Whitewater River cove; results of the 2-D modeling will be used to develop physical model boundaries of Lake Jocassee for three-dimensional (3-D) computational fluid dynamics (CFD) modeling.
- Use the CFD model to evaluate flows and the extent of vertical mixing in the Whitewater River cove and downstream of the submerged weir due to the addition of a second inlet/outlet structure.

Note that associated potential effects on shoreline erosion in the Whitewater River cove due to a second powerhouse were assessed during the preliminary feasibility study. Results indicated erosion on the bank opposite the inlet/outlet (I/O) structure would not be affected by additional flows; the final report was included in the RSP.

3 Study Area

The study area encompasses the western portion of Lake Jocassee that includes the Whitewater River arm and the Thompson River arm (Figure 3-1); this is the extent of the CFD model domain.

Figure 3-1. CFD Modeling Study Area

As described in the Bad Creek relicensing pre-application document, nearly half a million cubic yards of material from the original Project excavation was placed approximately 550 meters (1,804 feet [ft]) downstream of the Project's I/O structure to form a submerged weir. The function of the weir is to help minimize the effects of Project operations on the natural stratification of Lake Jocassee; the weir prevents the mixing of warmer water from the pumped storage discharge with the cooler water in the lower layer of the lake for the protection of coldwater fish habitat. The weir also serves to dissipate the energy of the discharging water from the I/O structure. Duke Energy is considering expanding the existing submerged weir in the downstream direction with newly excavated rockfill from the proposed Bad Creek II Complex. A

schematic drawing showing a profile of the existing weir in Whitewater River cove as well as the proposed expanded weir is depicted on Figure 3-2.

The Study Area includes three historic Duke Energy water quality monitoring stations (Stations 564.1, 564.0, and 560.0) in the Whitewater River arm of Lake Jocassee as shown on Figure 3-3. Water quality data (e.g., temperature, dissolved oxygen) from these monitoring stations are included in the Summary of Existing Water Quality Data and Standards Report, which was developed as a desktop study under Task 1 of the Water Resources Study and will be included in the Initial Study Report (ISR). Results from that study indicate the water column is completely mixed (i.e., no natural stratification) near the I/O structure upstream of the weir; however, just downstream of the weir, stratification is comparable to rest of the waterbody, indicating the weir is functioning as intended and mixing is confined to the Whitewater River cove upstream of the weir.

Figure 3-2. Submerged Weir in Whitewater River Cove (Existing and Proposed)

Figure 3-3. Water Quality Monitoring Stations in the Whitewater River Arm of Lake Jocassee

4 Methods and Model Description

4.1 2-D Model Development

A 2-D model was developed using Innovyze Infoworks Integrated Catchment Model (ICM) software (Innovyze Infoworks ICM Version 2023.2.0 [Innovyze 2023]) to evaluate the hydraulics of the Whitewater River cove with the goal of determining the CFD model boundary.

Because CFD modeling is a time-consuming process, the 2-D model was developed prior to the CFD model to more efficiently establish the required modeling extent (i.e., model domain). Results from the 2-D model were used as input into the CFD model to determine the downstream modeling boundary; the significantly reduced computational run time of the 2-D model was able to achieve this step in a single model run as opposed to a lengthy iterative process. The ICM software is considered appropriate to approximate the extent of hydraulic effects in the Whitewater River arm downstream of the submerged weir.

4.1.1 Modeling Approach

The ICM is a fully integrated 2-D hydrodynamic model which facilitates accurate representation of flow paths while enabling complex hydraulics and hydrology to be incorporated into a single model. The model uses the shallow water equations to develop depth-averaged hydraulic results. It does not directly model turbulence, but accounts for energy losses due to bed resistance via the Manning's n roughness coefficient. The model provides detailed hydraulic information and reasonable variability in average flow, depth, and velocity from one water column element to the next throughout the modeled area. For the Bad Creek study, scenarios assume full generation/pumping capacity for the entirety of the simulation.

Simulation length was determined by the time it takes to drain/fill the Bad Creek Reservoir from full pond to maximum drawdown (160 ft). The Bad Creek Reservoir usable storage ranges from elevation 2,310 ft to 2,150 ft and the usable storage volume is 31,808 acre-ft. Table 4-1 presents the simulation run times for various operating conditions under existing, upgraded, and proposed flowrates in cubic feet per second (cfs) using Bad Creek Reservoir storage of approximately 30,000 acre-ft. Upgraded conditions include an ongoing pump-turbine upgrade at the existing Project that will increase the total capacity by 280 megawatts (MW) (70 MW per unit). Proposed conditions refer to the existing Project plus the addition of Bad Creek II.

Table 4-1. Bad Creek Simulation Times

Powerhouse	Generation		Pumping	
Configuration	Max. Hydraulic Capacity (cfs)	Time (hours)	Max. Hydraulic Capacity (cfs)	Time (hours)
Existing	16,000	22.9	13,780	26.5
Upgraded	19,760	18.8	15,000	24.4
Proposed	39,200	9.3	32,720	11.2

4.1.2 Digital Terrain Model Development

The digital terrain model (DTM) used in the 2-D model was constructed with data from two sources:

- Bathymetry measurements collected in Lake Jocassee by Duke Energy in 2010;
- Light Detection and Ranging (i.e., LiDAR) data from the South Carolina Department of Natural Resources (SCDNR) online portal.

The data sources were converted into triangulated irregular network surface files and merged using Environmental Systems Research Institute (ESRITM) ArcGIS Pro version 2.8.8 Geographic Information System (GIS) software (ESRI 2021). The resulting DTM encompassed Lake Jocassee and was used in the 2-D and CFD models. The DTM is presented in Figure 4-1. For increased detail, Figure 4-1 shows the southern portion of Lake Jocassee, but the DTM used in the 2-D model includes the entirety of Lake Jocassee.

The process of creating the terrain model for both the existing and expanded weir geometry was the same; however, existing bathymetry data in the vicinity of the submerged weir and proposed powerhouse was replaced with the proposed weir geometry for the expanded weir model scenarios. The expanded weir and proposed powerhouse terrain model are shown in detail on Figure 4-2.

Figure 4-1. Digital Terrain Model of Lake Jocassee

Figure 4-2. Expanded Weir and Proposed Inlet/Outlet Structure Terrain Model

4.1.3 Mesh Development

The 2-D Zone defining the ICM Model includes Lake Jocassee and surrounding contours to elevation 1,120 ft above mean sea level (msl). Figure 4-3 provides a view of a portion of the 2-D Zone extent.

For the 2-D simulation, ICM subroutines were used to perform a meshing of the 2-D Zone. The 2-D mesh is comprised of an irregular array of triangles. Descriptions of the user input 2-D Zone data fields that are pertinent to this analysis are as follows:

- Minimum element area Minimum mesh element area used for calculating results. Mesh elements with area less than the minimum area specified are aggregated with adjoining elements until the minimum area is met. This is done for the purpose of calculating results to improve simulation stability and run time.
- Boundary points Boundary condition for 2-D Zone.
- Terrain-sensitive meshing Meshing is used to increase the resolution of the mesh in areas that have a large variation in height without increasing the number of elements in relatively flat areas.
- Maximum height variation The maximum height variation that is permitted within a single triangle. Triangles with a height variation greater than the assigned value are split provided this would not result in a triangle smaller than the minimum element area.
- Minimum triangle angle Minimum allowable angle between triangle vertices when creating a 2-D mesh.
- Roughness Manning's n roughness values, used when creating a 2-D mesh. The roughness value assigned to mesh elements in areas in the 2-D Zone that are not in a roughness zone. Roughness values were selected from published tables (Innovyze 2023).

Table 4-2 provides a summary of the selected user input values for the ICM meshing routine as well as the total 2-D Zone area.

2D zone Object Properties ■ Polygon definition ID Lake_Joc_2D -• 8063.583 #D Area (acre) Maximum triangle area (ft2) 100.000 Minimum element area (ft2) 50.000 * Mesh generation Classic Boundary points Vertical Wall #D * Terrain-sensitive meshing × -Maximum height variation (ft) 5.000 Minimum angle (degree) 25.00 #D * Roughness (Manning's n) 0.0400 • #D * Roughness definition Apply rainfall etc directly to mes #D Apply rainfall etc everywhere Rainfall profile 1 #D * Infiltration surface #D Turbulence model * #D Rainfall percentage #D * 100,000 Mesh summary -Mesh data General properties Notes 111 * Hyperlinks *** User defined properties

Table 4-2. ICM Meshing User Inputs and Area Summary

A section of the resulting mesh is shown on Figure 4-4. The model mesh contains 1,147,067 elements. The approximate minimum, average, and maximum, element areas are 9.3 ft², 18.2 ft², and 46.5 ft², respectively.

A uniform Manning's *n*-value of 0.04 was used for the entire model which is appropriate for modeling open water such as a large reservoir (Chow 1959).

Figure 4-3. Extent of 2-D Zone and ICM Mesh

Figure 4-4. Example of 2-D Model Mesh Section

4.1.4 2-D Model Scenarios

It was assumed the scenarios with the greatest effect on the Whitewater River cove would be those where Lake Jocassee was operating at minimum pond (elevation 1,080 ft msl). The extent of those hydraulic effects was then evaluated under the existing and proposed weir configuration (i.e., weir geometry). Table 4-3 presents the two scenarios analyzed with the 2-D model.

The conservative assumption that Jocassee Hydroelectric Station would operate to maintain the lake level at the target elevation (full pond/maximum drawdown) for the entirety of the simulation was used.

Scenario	Flowrate	Operating Mode	Submerged Weir Geometry
Existing	16,000 cfs	Generation	Existing
Proposed	39,200 cfs	Generation	Expanded

Table 4-3. 2-D Model Scenarios

4.2 CFD Model Development

FLOW-3D was developed and is supported by Flow Science, Inc. (Flow Science 2023) and is a commercially available computational model capable of solving three-dimensional (3-D) unsteady Reynolds Averaged-Navier Stokes equations. The software utilizes a Volume of Fluid method to calculate the free surface within the model domain (Hirt and Nichols 1981). The software package contains the meshing module (pre-processor), solver, and post-processor.

4.2.1 Modeling Approach

The FLOW-3D software solves unsteady Reynolds Averaged-Navier Stokes equations on structured grids and the governing equations used in the model are provided in the FLOW-3D user's guide (Flow Science 2023). A model-fitted mesh was developed for the model domain. Depending on the scenario, a specified water surface elevation (full pond or maximum drawdown) was applied to the upstream reservoir mesh boundary.

4.2.1.1 Pressure Solver Options

Two numerical schemes are available for the pressure solver module with multiple options (i.e., implicit and explicit). Within the implicit solver, limited compressibility models can be toggled

to relax the constraints of the pressure solver for cases where solution stability is an issue. The explicit solver allows for improved accuracy of the solution, though it results in longer computational time (Hirt 2000). The explicit pressure solver was applied in the Bad Creek II CFD modeling effort.

4.2.1.2 Turbulence Models

Various one-equation (Prandtl Mixing Length and Turbulent Energy Model) and two-equation (k-e, k-w, and Renormalized Group) turbulence modules are available in FLOW-3D (Yakhot and Orszag 1986). The Renormalized Group model was selected for the model based on anticipated flow patterns in the Whitewater River cove. Additionally, the Renormalized Group model is robust enough to handle the anticipated increased turbulence in the Whitewater River cove as a result of a second I/O structure.

4.2.1.3 Model Domain

The model domain was approximated using the 2-D model. Extents of hydraulic effects due to the operation of the second powerhouse were analyzed in the 2-D model, and the CFD model was appropriately sized based on that analysis. Detailed discussion of this analysis is presented in Section 5.2.

4.2.1.4 Model Limitations

The CFD model is a numerical approximation of hydraulic conditions and, as with all numerical models, results are a product of model input and assumptions. For instance, some hydrodynamic features cannot be precisely modeled, and turbulence closure models and recirculation patterns and vortices are approximate in size and strength; however, the selected features used to produce the results for this study are considered appropriate for the intended use of the model results.

4.2.2 Model Geometry

The DTM developed for the 2-D model was utilized in the CFD model. Detailed information on DTM development is presented in Section 4.1.2.

CFD models can be sensitive to shallow depths. Model iteration convergence is challenging when the depth of water in a given mesh cell is low compared to the mesh size. More discussion of the model mesh is presented in the following section, but to achieve reasonable run times for this model, a larger mesh was used.

Because shorelines can be difficult to resolve, geometry modifications were made along the shoreline of the CFD model. Vertical walls were assumed along the shoreline starting 10 ft below the target elevation (i.e., 1,070 ft msl) for the minimum pond level, and 1,100 ft msl for the full pond level. This modification ensured that a minimum depth of 10 ft was present throughout the model, and significantly improved model stability and simulation run times. An example of vertical walls at full pond is shown on Figure 4-5.

Figure 4-5. CFD Model Geometry with Vertical Walls

4.2.3 Mesh Development

The CFD model determines flow field throughout the volume of water in discrete sections. A computational mesh is used to discretize the solution within the domain. FLOW-3D requires the computational mesh to be comprised of orthogonal elements (faces align with the x, y, or z direction). The model topography and features were translated to represent significant features with fewer elements.

The CFD model domain covers approximately 922 acres. To manage simulation run times for a model of this size, a coarse mesh was required. As a general rule with CFD modeling, there is a trade-off between computational run time and mesh density. A denser, more refined mesh will

more accurately resolve complicated hydraulic phenomena such as vortices and turbulence. A coarser mesh will have less resolution of these features but allows the model domain to be much larger without creating unreasonable model simulation times.

Flow in Lake Jocassee is deep, and very slow, meaning a coarse mesh is appropriate for the CFD model. The computational mesh block used was 20-ft by 20-ft by 10-ft (length by width by height). Figure 4-6 presents a plan and profile view of the model mesh in the vicinity of the existing submerged weir.

Figure 4-6. CFD Model Mesh

4.2.4 Model Scenarios

Sixteen scenarios listed in Table 4-4 were evaluated to help determine effects of Project operations on vertical mixing in the Whitewater River arm. Scenarios modeled the existing and expanded submerged weir configuration in both generating and pumping mode; and at full pond (elevation 1,110 ft msl) and maximum drawdown (elevation 1,080 ft msl). Results under full pond and maximum drawdown provide potential upper and lower limits of hydraulic effects of Bad Creek II operations. Figure 4-7 provides an exceedance plot of the Lake Jocassee pond level from 1975 to 2020. This plot shows the percentage of time the reservoir is at or above a given elevation. Lake Jocassee operates within 5 ft of the full pond elevation of 1,110 ft roughly 50

percent of the time, and in the 45-year period of record Lake Jocassee has never reached the

Table 4-4. CFD Model Scenarios

minimum drawdown elevation.

Station	Operating Mode	Submerged Weir Geometry	Scenario	Flow (cfs)	Jocassee Reservoir Elevation (ft msl)

4.2.5 Boundary Conditions

Boundary conditions for the CFD model were applied through multiple boundary types; boundary types are briefly described in the following sections. Boundary condition definitions were consistent between existing and proposed model configurations.

4.2.5.1 Volume Flowrate

A volume flowrate boundary condition was used to define the upstream boundary of the model where generation flows enter the Whitewater River cove, and where pumping flows exit the model extent. Because the focus of this model is to determine hydraulic effects downstream of the submerged weir, detailed resolution of the hydraulics in the vicinity of the I/O structures was not necessary. The inflow to the CFD model was held constant throughout the scenarios and assumed to be a uniform flow pattern approaching the weir at a scenario's specific flowrate.

Additionally, the long-term average flowrate from the Thompson River arm was included in the model to incorporate flows downstream of the weir. Because there is no gaging station on the Thompson River near Lake Jocassee, a drainage area proration² was performed between the now-retired U.S. Geological Survey (USGS) Howard Creek gage (USGS 02184475) (2.16 square miles [mi²]) and the Thompson River (11.6 mi² at confluence with Lake Jocassee). Data from the Howard Creek gage extend from 1988 to 1996. Monthly average flows in the Thompson River range from 10 cfs to 130 cfs with an annual average of 40 cfs. This 40 cfs was introduced to the model at the upstream end of the Thompson River arm. Table 4-5 presents the prorated monthly average Thompson River flows entering Lake Jocassee.

Table 4-5. Thompson River Prorated Average Monthly Flows (cfs)

4.2.5.2 Outflow Boundary

The outflow boundary was applied to the downstream limit of the model. This boundary allows pressure to be balanced through the model. A hydrostatic pressure condition was applied at the outflow and set to the target reservoir water surface elevation of 1,110 or 1,080 ft msl for the full and maximum drawdown Lake Jocassee levels, respectively.

It was assumed that Jocassee operations would maintain the target pond elevation (full pond/maximum drawdown) for the entirety of the simulation.

² The drainage-area ratio method commonly is used to estimate streamflow for sites where no streamflow data are available using data from one or more nearby streamflow-gaging stations.

4.2.5.3 Boundary Type Wall

The boundary type wall applied the no-slip condition at the outer boundary of the mesh blocks as well as a zero-velocity condition normal to the boundary.

4.2.6 CFD Simulation Evaluation

Model runs focused on the flow patterns and velocities downstream of the submerged weir. Multiple methods were used to monitor the progress of the model during the simulation. This section highlights the methods used to evaluate the model during the simulation and in post-processing. Flux surfaces and monitoring points provided data during the simulations.

4.2.6.1 Flux Surfaces

Flux surfaces were used to monitor the volumetric flow through over the weir and near the model outlet. The flux surfaces are vertical planes placed at specific locations in the CFD model. The surfaces were monitored for mass/volume balance of flow through the model.

4.2.6.2 Monitoring Points

Monitoring points were placed within the model to gather point data in Lake Jocassee during model simulations. Modeled velocities and water surface elevations were actively monitored during the simulation to track model stability.

4.2.7 Model and Scenario Evaluation

4.2.7.1 Model Verification

An acoustic Doppler current profiler (ADCP) was used to measure velocities throughout the water column along transects in the Whitewater River arm in July and August of 2023 under pumping and generation. Operations data (i.e., individual unit generation in megawatts, forebay elevation, and tailwater elevation) during field data collection were obtained from Duke Energy for Bad Creek and Jocassee Hydro Station. The field conditions were compared to modeled scenarios and, where appropriate, transects of modeled velocity were compared qualitatively against the field data. Preliminary evaluations of the data show the CFD model is a reasonable numerical estimation of flow patterns and velocities in the Whitewater River arm.

Model verification scenarios will be built using operations and reservoir elevation data from the time of the field data collection to present a range of error or confidence in the modeled results. These runs will provide a direct comparison between the modeled and field data under the same hydraulic conditions. This analysis will be performed in fall of 2023; an addendum to the study report will be provided with the final report.

4.2.7.2 Reservoir Elevation Criteria

The purpose of analyzing two reservoir elevations (i.e., pond levels) was to determine if the hydraulic effects vary between minimum and maximum water surface elevations (i.e., 1,080 ft msl and 1,110 ft msl, respectively). Flow velocity or other hydraulic thresholds or criteria were not established, and for a given operating configuration hydraulic results were directly compared between reservoir elevations.

4.2.7.3 Operation Mode Criteria

Pump and generation operating modes were analyzed with the CFD model. Scenarios were compared against each other to assess how pumping and generating affect the hydraulics downstream of the submerged weir. No specific hydraulic thresholds or criteria were established for the comparison.

4.2.7.4 Submerged Weir Geometry

The effect of varying the submerged weir geometry was studied using the CFD model. Scenarios were compared against each other to assess how the geometry of the submerged weir affects the flow patterns and vertical mixing downstream of the weir. No specific hydraulic thresholds or criteria were established for the comparison.

4.3 Previous CFD Modeling – Upper Whitewater River Cove

As part of the Bad Creek II Feasibility Study authorized by Duke Energy, a three-dimensional CFD model for the lower reservoir (i.e., Lake Jocassee) was developed to support the evaluation of a second additional I/O structure and the potential associated effects on the Whitewater River

cove of Lake Jocassee. ³ The model boundary for this effort included the area of Whitewater River cove immediately downstream of the I/O structure for the purpose of establishing velocity and flow patterns in the channel and near the east bank of the cove opposite of the discharge structure.

The CFD modeling framework included a calibration phase (phase I) focused on replicating the existing dominant flow and velocity patterns predicted by the Alden Research Laboratory physical model (Larsen and White 1986), followed by phase II, which focused on evaluating the velocity and flow pattern effects of the proposed second I/O structure at two reservoir elevations (1,110 ft and 1,080 ft msl). The second phase utilized discharge flows based on the upgraded Bad Creek units, plus the assumed discharge from the conceptualized Bad Creek II project.

Unit operations in both the turbine and pump mode were simulated with the existing and proposed structures at reservoir levels 1,110 ft msl, 1,096 ft msl, and 1,080 ft msl. Model results indicated that velocities produced by full generation from the existing project at the upper and lower reservoir levels are similar to the velocities physically modeled in 1986. Additional discharge from proposed Bad Creek II operations created a concentrated area of higher velocity flows extending downstream to the existing Bad Creek I/O structure. As expected, this effect was more pronounced at lower reservoir levels. The concentrated area of high velocity and change in location of velocities would not affect existing bank conditions/erosion assuming the geology of the east bank is consistent along the shoreline (i.e., predominantly exposed bedrock). Additional scenarios to simulate pumping operations were performed and showed distinct flow patterns specific to each I/O structure. Velocities and flow patterns in the water column near the expanded submerged weir structure were qualitatively evaluated; velocities increased as the flow depth decreased. Velocities along the eastern bank near the expanded weir were higher when compared to the simulations using the existing weir due to the increased generation flows.

³ The Lower Reservoir CFD Flow Modeling Report (HDR 2022) was filed with the RSP as Appendix I.

5 2-D Model Results

5.1 Hydraulic Effects

The results of the 2-D modeling scenarios are presented on Figure 5-1. Flow vectors colored and sized by velocity are shown for both the existing (left) and proposed (right) scenarios. While velocities of approximately 1.0 ft per second (fps) are shown in the vicinity of the I/O structure and extending across the top of the submerged weir, velocities decrease to approximately 0.2 fps by the time existing generation flows reach the confluence of the Whitewater River arm and the Thompson River arm of Lake Jocassee. For the proposed generation scenario, velocities of approximately 0.2 fps extend about 5,000 ft further downstream, above the confluence with the Devil's Fork arm. As water always follows the path of least resistance, the area of increased velocity follows the original thalweg of the river.

Figure 5-1. 2-D Model Results for Existing (Bad Creek) and Proposed (Bad Creek II) Conditions

5.2 CFD Model Domain

A key purpose of the submerged weir is to dissipate energy and force flows from the Bad Creek I/O structure to the surface of Lake Jocassee (to minimize vertical mixing in the water column downstream of the weir). Because the 2-D model is depth-averaged, the effect of forcing water to the surface over the weir is not fully predicted. To account for the 2-D model's potential underestimation of the extent of hydraulic effects, the CFD model domain was extended approximately 0.5 mile further downstream. Figure 5-2 outlines the approximate CFD model domain.

The CFD model domain volume is approximately 133,000 acre-ft, while the full-pond volume of Lake Jocassee is about 1.2 million acre-ft. The model represents approximately 11 percent of the total volume of the lake. The relative size of the portion of the lake affected by the Project is important to consider when analyzing the effects of proposed powerhouse operations.

There are approximately five river miles between the Whitewater River and the Lake Jocassee dam. The model domain includes a third of this distance. Figure 5-3 shows a profile of the five miles from the Whitewater River to the dam, highlighting the modeled section.

Figure 5-2. Approximate CFD Model Domain

Figure 5-3. Lake Jocassee Profile from the Whitewater River to Jocassee Dam

6 CFD Model Results

6.1 Domain Verification

To confirm the CFD model domain was appropriately sized, the hydraulic profile at the model exit was compared across three scenarios:

- Existing generation with existing submerged weir;
- Proposed generation with existing submerged weir;
- Proposed generation with expanded submerged weir.

Figure 6-1 shows the CFD model domain plan view as well as a vertical slice near the downstream boundary of the model (green). The exit hydraulic profile for the three scenarios was taken at this slice location. When comparing proposed versus existing generation scenarios, the average exit velocity at the downstream extent of the CFD model domain is < 0.1 fps higher on average for the proposed generation scenario (range -0.06 fps to +0.15 fps). This represents a reasonable trade-off in modeling results versus modeling effort as extending the model domain

further would not result in additional useful information but would greatly increase the overall modeling effort (including model run time). The small incremental increase in average velocity at the CFD model domain exit due to the proposed generation is much less than incremental velocity effects due to meteorological conditions (i.e., wind-induced effects in the upper water surface layer). Figure 6-2 compares three profiles (i.e., slices) representing three scenarios (existing, proposed with existing weir, and proposed with expanded weir) at the downstream model domain boundary.

Velocity profiles across the three scenarios are nearly identical and show very low (< 0.2 fps) velocities. Two conclusions are made from these results:

- 1. Because velocities are so low, the model domain has been extended far enough downstream to fully capture hydraulic effects of existing and proposed powerhouse operations.
- 2. Potential hydraulic effects discussed in this report are limited to the model domain (i.e., there are no appreciable hydraulic effects to Lake Jocassee downstream of the model domain).

Figure 6-1. Comparison Slice Location (green)

Figure 6-2. Model Exit Hydraulic Profile Comparison

6.2 **Existing Project Configuration**

To establish a baseline for comparison, the existing Bad Creek configuration and operations were modeled under full pond and maximum drawdown. Scenarios included the maximum generating flow of 16,000 cfs, the maximum pumping flow of 13,780 cfs, and the existing submerged weir geometry. Simulation times for the existing generation and pumping scenarios are 22.9 and 26.5 hours, respectively (see Table 4-1).

The four upgraded powerhouse scenarios (Scenarios 13-16 in Table 4-4) figures are presented in Appendix A. Results from these scenarios are consistent with the other 12 scenarios.

6.2.1 Generation

Full Pond

Existing hydraulic conditions at the full pond elevation are characterized by low flow velocities throughout the model domain. Flow velocities peak across the top of the submerged weir at approximately 0.6 fps. Figure 6-3 shows contours of velocity in an aerial view. Figure 6-4 shows the surface velocity contours in the vicinity of the submerged weir, as well as two vertical slices showing vertical velocity profiles in the Whitewater River arm⁴.

Slice A-A' is located approximately across the crest of the submerged weir, and slice B-B' is approximately 800 ft downstream of slice A-A'.

Figure 6-5 presents hydraulic flow paths with velocity magnitudes identified by color (in fps) in the Whitewater River cove. For reference, water quality monitoring stations 564.1 and 564.0 are shown on the figure. Dense areas of streamlines downstream of the submerged weir indicate an area of potential mixing that extends approximately 850 ft downstream of the submerged weir.

More information on water quality and mixing at existing monitoring stations in the Whitewater River cove is provided in the Summary of Existing Water Quality and Standards Report (provided in Appendix A of the ISR). Results from the desktop water quality study indicate that flow is well mixed (i.e., lacks stratification) upstream of the weir at water quality monitoring location 564.1 but stratification is present throughout the year at monitoring location 564.0 just downstream of the weir. Results of the CFD modeling align with these field data observations. While flow appears to be mixing downstream of the submerged weir, velocities are very low (less than 0.25 fps) in the reservoir between the weir and monitoring location 564.0. Because the weir dissipates energy from Bad Creek I/O structure, the slow-moving uniform flow regime downstream of the weir creates conditions suitable for vertical stratification, similar to what occurs at other monitoring stations in the main body of Lake Jocassee. This effect (i.e., mixing on the upstream of the weir and vertical stratification on the downstream side) is present across the range of simulations evaluated.

⁴ For all vertical slices, viewer perspective includes the viewer standing downstream of the slice looking upstream.

Figure 6-3. Existing Generation at Full Pond – Velocity Contours

Figure 6-4. Existing Generation at Full Pond – Velocity Contours in Submerged Weir Vicinity (Flow is Left to Right)

Figure 6-5. Existing Generation at Full Pond – Whitewater River Cove Streamlines (Flow is Left to Right)

Maximum Drawdown

At maximum drawdown, the effect of the submerged weir is more pronounced. Surface velocity contours show an area of slightly elevated velocity in the immediate vicinity of the submerged weir. This area of slightly elevated velocity extends approximately 200 ft from the weir crest and peaks at 1.1 fps. This area of elevated velocity is shown on Figure 6-6 and Figure 6-7. Vertical slices A-A' and B-B' in Figure 6-7 indicate the area of higher velocity is present through the majority of the water column across the top of the weir, but as flow expands into the downstream section of the Whitewater River Cove, this effect has dissipated. Figure 6-8 shows hydraulic flow paths with velocity magnitudes identified by color which have a similar flow pattern to those shown in Figure 6-5 (full pond streamlines), however the effect of the weir is more pronounced. At lower reservoir elevations (i.e., pond levels), water velocities are accelerated across the top of the weir as flows are forced to the surface. This results in an area of slightly higher surface velocities, and a slightly shorter potential mixing length downstream of the weir.

As with the full pond scenario, the weir limits downstream mixing and because of the very low velocities downstream of the weir, stratification trends at monitoring station 564.0 mimic the rest of Lake Jocassee.

Figure 6-6. Existing Generation at Maximum Drawdown – Velocity Contours

Figure 6-7. Existing Generation at Maximum Drawdown – Velocity Contours in Submerged Weir Vicinity (Flow is Left to Right)

Figure 6-8. Existing Generation at Maximum Drawdown – Whitewater River Cove Streamlines (Flow is Left to Right)

6.2.2 Pumping

Full Pond

Existing pumping conditions at full pond are similar to existing generation conditions at full pond. Low velocities are seen throughout the model domain, and peak across the top of the submerged weir at approximately 0.5 fps. Surface velocities are shown in Figure 6-9 and Figure 6-10, and the same vertical slices A-A' and B-B' presented in previous figures are shown on Figure 6-10. Hydraulic flow paths with velocity magnitudes identified by color in the Whitewater River cove are presented in Figure 6-11. There is little to no vertical mixing downstream of the submerged weir under pumping operations. As flow is pumped to Bad Creek Reservoir, it is gradually pulled from the upper surface layer of Lake Jocassee over the submerged weir resulting in a very uniform, laminar flow regime downstream of the weir. Flow patterns at monitoring location 564.0 extending upstream to the weir are uniform and have velocities less than 0.2 fps indicating seasonal stratification would be maintained throughout the reservoir downstream of the weir.

Figure 6-9. Existing Pumping at Full Pond – Velocity Contours

Figure 6-10. Existing Pumping at Full Pond – Velocity Contours in Submerged Weir Vicinity (Flow Right to Left)

Figure 6-11 Existing Pumping at Full Pond – Whitewater River Cove Streamlines (Flow Right to Left)

Maximum Drawdown

Similar to generating at maximum drawdown, pumping at maximum drawdown increases the effect of the submerged weir. An area of higher velocity extends approximately 1,200 ft upstream of the submerged weir peaking at 1.9 fps. Surface velocities for pumping at maximum drawdown are shown in Figure 6-12 and Figure 6-13. Vertical slices in Figure 6-13 indicate minimal vertical mixing effects are observed downstream of the submerged weir. Velocity streamlines in the Whitewater River cove shown on Figure 6-14 are uniform and slow moving, indicating stratification would be present downstream of the weir. As flow is pulled across the top of the weir it is accelerated near the surface into the upstream section of the Whitewater River cove.

Figure 6-12. Existing Pumping at Maximum Drawdown – Velocity Contours

Figure 6-13. Existing Pumping at Maximum Drawdown – Velocity Contours in Submerged Weir Vicinity (Flow Right to Left)

Figure 6-14. Existing Pumping at Maximum Drawdown – Whitewater River Cove Streamlines (Flow Right to Left)

6.3 Proposed Project, Existing Weir

6.3.1 Generation

Full Pond

The proposed generation flow is more than double the existing flow (39,200 cfs vs 16,000 cfs). This significant increase in flow results in a localized increase in velocity at the surface and through the water column. Conditions at the full pond elevation are characterized by low flow velocities throughout the model domain. Flow velocities peak across the top of the submerged weir at approximately 1.4 fps. Figure 6-15 shows contours of velocity in an aerial view. Figure 6-16 shows the surface velocity contours in the vicinity of the submerged weir, as well as the two vertical slices showing vertical velocity profiles in the Whitewater River arm. The area of elevated velocity (1-2 fps) extends approximately 1,000 ft downstream of the weir crest.

Figure 6-17 presents hydraulic flow paths with velocity magnitudes identified by color in the Whitewater River cove. Note water quality monitoring points 564.1 and 564.0 are shown on the figure. The dense areas of streamlines downstream of the submerged weir indicates that an area of potential mixing extends approximately 850 ft downstream of the submerged weir, which is a similar mixing length as existing generation at full pond. While flow appears to be mixing downstream of the submerged weir, velocities are very low, less than 0.25 fps, between the weir and monitoring location 564.0. These slow, uniform flow patterns are very similar to existing conditions and facilitate conditions for stratification within the water column at water quality monitoring station 564.0 just downstream of the weir.

Figure 6-15. Proposed Generation (Existing Weir) at Full Pond – Velocity Contours

Figure 6-16. Proposed Generation (Existing Weir) at Full Pond – Velocity Contours in Submerged Weir Vicinity (Flow is Left to Right)

Figure 6-17. Proposed Generation (Existing Weir) at Full Pond – Whitewater River Cove Streamlines (Flow is Left to Right)

Maximum Drawdown

At maximum drawdown, the effect of the submerged weir is more pronounced. Contours of surface velocity show an area of slightly elevated velocity in the immediate vicinity of the weir. This area of slightly elevated velocity extends downstream approximately 2,100 ft from the weir crest and peaks at 3.7 fps. This area of elevated velocity is shown on Figure 6-18 and Figure 6-19. Vertical slices A-A' and B-B' shown on Figure 6-19 indicate the area of higher velocity is present through the majority of the water column across the top of the weir, but as flow expands into the downstream section of the Whitewater River cove, flow is concentrated on the right descending bank, and only in this section are velocities elevated throughout the water column. Figure 6-20 shows hydraulic flow paths with velocity magnitudes identified by color which have a similar flow pattern as shown in Figure 6-17 (full-pond streamlines), however the effect of the weir is more pronounced. At lower pond levels, water velocities are accelerated across the top of the weir and flows are forced to the surface. This results in an area of slightly higher surface velocities, and a slightly shorter potential mixing length downstream of the weir.

As with the full pond scenario, because of the very low velocities downstream of the weir at water quality monitoring location 564.0, it can be reasonably expected that flow conditions would promote stratification.

Figure 6-20. Proposed Generation (Existing Weir) at Maximum Drawdown – Whitewater River Cove Streamlines (Flow is Left to Right)

6.3.2 Pumping

Full Pond

The proposed pumping flow is more than double the existing flow (32,720 cfs vs 13,780 cfs). This significant increase in flow results in a localized increase in velocity at the surface and through the water column. Conditions at the full pond elevation are characterized by low flow velocities throughout the model domain. Flow velocities peak across the top of the submerged weir at approximately 1.1 fps. Figure 6-21 shows contours of velocity in an aerial view. Figure 6-22 shows the surface velocity contours in the vicinity of the submerged weir, as well as the two vertical slices showing vertical velocity profiles in the Whitewater River arm. The area of elevated velocity (1-2 fps) extends approximately 160 ft upstream of the weir crest.

Figure 6-23 presents hydraulic flow paths with velocity magnitudes identified by color in the Whitewater River cove. There is little to no vertical mixing downstream of the submerged weir under pumping operations. As flow is pumped to Bad Creek Reservoir, it is gradually pulled from Lake Jocassee across the top of the submerged weir resulting in a very uniform, laminar flow regime downstream of the weir. Flow patterns at monitoring location 564.0 extending upstream to the weir are uniform and have velocities less than 0.2 fps indicating stratification would be present throughout the reservoir downstream of the weir.

Figure 6-23. Proposed Pumping (Existing Weir) at Full Pond – Whitewater River Cove Streamlines (Flow is Right to Left)

FDS

Maximum Drawdown

Similar to generating at maximum drawdown, pumping at maximum drawdown increases the effect of the submerged weir. An area of higher velocity extends approximately 1,200 ft upstream of the submerged weir peaking at 1.9 fps. Surface velocities for pumping at maximum drawdown are shown in Figure 6-24 and Figure 6-25. Vertical slices in Figure 6-25 indicate minimal vertical mixing effects are observed downstream of the submerged weir. Velocity streamlines in the Whitewater River cove shown on Figure 6-26 are uniform and slow moving, indicating stratification would be present downstream of the weir. As flow is pulled across the top of the weir it is accelerated into the upstream section of the Whitewater River cove.

Figure 6-26. Proposed Pumping (Existing Weir) at Maximum Drawdown – Whitewater River Cove Streamlines (Flow is Right to Left)

6.4 Proposed Project, Expanded Weir

6.4.1 Generation

Full Pond

The proposed expanded submerged weir has a slightly stronger effect of accelerating flow across the top of the weir and downstream into the lower Whitewater River cove. Similar to the existing weir configuration, full-pond hydraulic conditions in the Whitewater River cove under proposed flow with the expanded weir geometry are characterized by relatively low velocities. Flow velocities peak across the top of the submerged weir at approximately 1.3 fps. Figure 6-27 shows contours of velocity in an aerial view. Figure 6-28 shows the surface velocity contours in the vicinity of the submerged weir, as well as two vertical velocity profiles in the Whitewater River arm. Slice B-B' indicates an area of elevated velocity is present in the water column 800 ft downstream of the submerged weir, however it is confined to the top portion of the water column, indicating the proposed weir is functioning as intended. The area of slightly elevated velocity (1.0-2.0 fps) extends about 1,800 ft downstream of the submerged weir.

Figure 6-29 presents hydraulic flow paths with velocity magnitudes identified by color in the Whitewater River cove. Dense areas of streamlines downstream of the submerged weir indicate an area of potential mixing that extends approximately 1050 ft downstream of the submerged weir. While flow appears to be mixing downstream of the submerged weir, velocities are very low, less than 0.25 fps, in the reservoir between the weir and monitoring location 564.0. These slow, uniform flow patterns allow for stratification to be established within the water column at water quality monitoring location 564.0. When compared to Figure 6-20, expanding the weir geometry results in flow patterns and magnitudes that are similar to the flow patterns and magnitudes of the existing submerged weir geometry, which limits downstream vertical mixing.

Figure 6-27. Proposed Generation (Expanded Weir) at Full Pond – Velocity Contours

Figure 6-28. Proposed Generation (Expanded Weir) at Full Pond – Velocity Contours in Submerged Weir Vicinity (Flow is Left to Right)

Figure 6-29. Proposed Generation (Expanded Weir) at Full Pond – Whitewater River Cove Streamlines (Flow is Left to Right)

Maximum Drawdown

The scenario with the proposed generating flow and expanded weir at maximum drawdown presents the greatest effect to water velocities and flow patterns in Whitewater River cove. With the lowered pond level, expanded weir geometry (in the downstream direction) and higher flowrate, the effect of the expanded weir is the most pronounced. Contours of surface velocity show an area of elevated velocity in the immediate vicinity of the weir. This area of slightly elevated velocity extends approximately 2,500 ft from the weir crest and peaks at 4.5 fps. For context, 4.5 fps is approximately 3.0 miles per hour or roughly the average adult walking speed.

The area of elevated velocity is shown on Figure 6-30 and Figure 6-31. Vertical slices A-A' and B-B' on Figure 6-31 indicate the area of higher velocity is present through the majority of the water column across the top of the weir, but as flow expands into the downstream section of the Whitewater River cove, flow is concentrated on the right descending bank and near the surface. Velocities in the Whitewater River cove are between 2.0-3.0 fps approximately 1,500 ft downstream of the submerged weir but are concentrated at the surface indicating little downstream mixing potential.

Figure 6-32 shows velocity streamlines that have a similar flow pattern as Figure 6-29 (full pond streamlines), however the effect of the weir is more pronounced. At lower pond levels, water velocities are accelerated across the top of the weir and flows are forced to the surface. This results in an area of slightly higher surface velocities, and a significantly reduced potential mixing length downstream of the weir.

As with the full pond scenario, because of the low velocities within the water column downstream of the weir at water quality monitoring location 564.0, it can be reasonably expected that flow conditions would not inhibit thermal stratification.

Figure 6-30. Proposed Generation (Expanded Weir) at Maximum Drawdown – Velocity Contours

Figure 6-31. Proposed Generation (Expanded Weir) at Maximum Drawdown – Velocity Contours in Submerged Weir Vicinity (Flow is Left to Right)

Figure 6-32. Proposed Generation (Expanded Weir) at Maximum Drawdown – Whitewater River Cove Streamlines (Flow is Left to Right)

6.4.2 Pumping

Full Pond

The expanded weir has a slightly stronger effect of accelerating flow across the top of the weir and upstream into the upper Whitewater River cove. Full pond pumping hydraulic conditions in the Whitewater River cove under the proposed flow with the expanded weir geometry are still characterized by relatively low velocities. Flow velocities peak across the top of the submerged weir at approximately 1.1 fps. Figure 6-33 shows contours of velocity in an aerial view. Figure 6-34 shows the surface velocity contours in the vicinity of the submerged weir, as well as two vertical slices showing vertical velocity profiles in the Whitewater River Arm. Slice B-B' indicates little to no elevated velocities downstream of the submerged weir. The area of slightly elevated velocity (1-2 fps) extends 200 ft upstream of the submerged weir.

Figure 6-35 presents hydraulic flow paths with velocity magnitudes identified by color in the Whitewater River cove. There is little to no vertical mixing downstream of the submerged weir under pumping operations. As flow is pumped to Bad Creek Reservoir, it is gradually pulled from Lake Jocassee across the top of the submerged weir resulting in a very uniform, laminar flow regime downstream of the weir. Flow patterns at monitoring location 564.0 extending upstream to the weir are uniform and have velocities less than 0.2 fps indicating stratification would be present throughout the reservoir downstream of the weir. When comparing to Figure 6-26, expanding the weir geometry results in flow patterns and magnitudes that are similar to the flow patterns and magnitudes of the existing submerged weir geometry, which limits downstream vertical mixing.

Figure 6-33. Proposed Pumping (Expanded Weir) at Full Pond – Velocity Contours

Figure 6-34. Proposed Pumping (Expanded Weir) at Full Pond – Velocity Contours in Submerged Weir Vicinity (Flow is Right to Left)

Figure 6-35. Proposed Pumping (Expanded Weir) at Full Pond – Whitewater River Cove Streamlines (Flow is Right to Left)

Maximum Drawdown

Similar to generating at maximum drawdown, pumping at maximum drawdown increases the effect of the submerged weir. An area of higher velocity extends approximately 1,800 ft upstream of the submerged weir peaking at 3.3 fps. Surface velocities for pumping at maximum drawdown are shown in Figure 6-36 and Figure 6-37. Vertical slices in Figure 6-37 indicate minimal vertical mixing effects are observed downstream of the submerged weir. Velocity streamlines in the Whitewater River cove shown on Figure 6-38 are uniform and slow moving, indicating stratification would be present downstream of the weir. As flow is pulled across the top of the weir it is accelerated into the upstream section of the Whitewater River cove.

Figure 6-36. Proposed Pumping (Expanded Weir) at Maximum Drawdown – Velocity Contours

Figure 6-37. Proposed Pumping (Expanded Weir) at Maximum Drawdown – Velocity Contours in Submerged Weir Vicinity (Flow is Right to Left)

Figure 6-38. Proposed Pumping (Expanded Weir) at Maximum Drawdown – Whitewater River Cove Streamlines (Flow is Right to Left)

6.5 Effect of Submerged Weir Geometry

As previously stated, the expanded weir geometry results in a small increase in flow acceleration as water flows over the crest of the weir (when compared to the existing weir geometry). Comparison of Figure 6-19 and Figure 6-31 shows similar magnitudes of velocity increases, but the area of elevated surface velocity are slightly larger with the expanded weir geometry. Comparison of streamlines downstream of the weir in Figure 6-20 and Figure 6-32 indicate the flow patterns are very similar, and it can be reasonably expected to result in similar stratification patters at water quality monitoring location 564.0.

Comparison of the pumping scenarios leads to the same conclusion. Flow is accelerated over the expanded weir and the increased velocity has a slightly larger footprint compared to the existing weir (Figure 6-25 vs Figure 6-31). However, expanding the weir geometry results in flow patterns and magnitudes that are similar to the flow patterns and magnitudes of the existing submerged weir geometry, which limits downstream vertical mixing. (Figure 6-26 vs Figure 6-38).

7 Conclusions

Each CFD model scenario was run at full pond and maximum drawdown. These two elevations were selected to bookend the potential operating conditions of the existing and proposed powerhouse configurations. Over the last 45 years, Lake Jocassee elevation has been above the minimum pond level 100 percent of the time.

The CFD model domain was appropriately sized to evaluate the hydraulic effects of Bad Creek and Bad Creek II. Results indicate hydraulic effects in Lake Jocassee due to operations are limited to the model domain (i.e., the area upstream of the Devil's Fork arm and Whitewater River arm confluence) and water conditions to maintain natural stratification downstream of the weir exist under all modeled scenarios.

In generation mode, the energy of the water discharged from Bad Creek is dissipated as it is forced across the top of the existing submerged weir. Similar vertical mixing patterns result from the existing and proposed expanded weir geometries under existing and proposed generation flows. Model results indicate Bad Creek II powerhouse operations will not alter existing

stratification patterns observed at Station 564.0 (downstream of weir) or further downstream into Lake Jocassee.

In pumping mode, hydraulic effects due to Bad Creek II operations are limited to the Whitewater River cove upstream of the submerged weir and in the upper water column across the top of the weir. No modeled configuration of pumping operations creates mixing downstream of the submerged weir. Water quality profile data (current and historic) also support CFD model results, indicating stratification is preserved downstream of the submerged weir. As discussed in Section 4.2.7.1, the CFD model will be verified with new computational runs simulating field conditions at the time of data collection. Preliminary verification model runs indicate good agreement between CFD results and velocity data collected in the Whitewater River arm.

8 Future Work

Model verification will be completed in fall 2023 and results will be provided in an addendum to the final study report.

9 Variances from FERC-approved Study Plan

There were no variances from the FERC-approved RSP.

1 Project Introduction and Background

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir and Lake Jocassee, which is licensed as part of the Keowee-Toxaway Hydroelectric Project (FERC Project No. 2503), as the lower reservoir. The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977 and expiration date of July 31, 2027.

Task 3 of the Water Resources Study (Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse) implemented three-dimensional (3-D) computational fluid dynamics (CFD) to determine flows and extent of vertical mixing in the Whitewater River cove (also called Whitewater River arm) due to the addition of a second powerhouse (Bad Creek II Power Complex [Bad Creek II]). Field verification data for the model were collected during summer 2023; however, results were not available prior to submittal of the Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse draft report (i.e., CFD Model Report) to stakeholders on September 11, 2023. Therefore, Duke Energy is hereby providing enclosed verification results as an addendum to the final CFD Model Report.

2 Objectives

The main objective of Task 3 of the Water Resources Study (i.e., CFD modeling) is to evaluate flow patterns and the extent of vertical mixing in the Whitewater River cove downstream of the submerged weir due to the addition of a second inlet/outlet structure. The purpose of this addendum is to provide a summary of field methods and results of flow and velocity data collected in the Whitewater River cove with the goal of verifying CFD model results, thereby providing confidence in modeled results.

3 Study Area

The study area for the CFD modeling study is shown on Figure 3-1. It encompasses the western portion of Lake Jocassee that includes the Whitewater River arm and the Thompson River arm; this is the extent of the CFD model domain previously presented in the CFD report.

Verification flow data were collected along four transects in the Whitewater River cove as shown on Figure 3-2. Approximate locations of flow transects include Transect 1 (upstream of the weir near water quality monitoring Station 564.1), Transect 2 (across the top of the submerged weir), Transect 3 (downstream of the submerged weir near Station 564.0), and Transect 4 at the confluence of the Whitewater River arm and Thompson Creek arm.

4 Methods

4.1 ADCP Overview

An Acoustic Doppler Current Profiler (ADCP) was used to measure flow velocities along four transects in Whitewater River arm (see Figure 3-2). ADCPs are versatile, widely used instruments for collecting flow measurement profiles in riverine or offshore marine environments; they do not measure the movement of water itself, but instead use sound waves produced by a transducer to measure the speed and direction of currents in the water column. It does this by sending out pulses of sound at a constant frequency and "listening" for echoes (i.e., backscatter) that reflect off particles in the water (typically zooplankton, suspended sediment, or other particles). The echoes have a slightly different frequency than the original sound transmitted, depending on whether the particles are moving towards or away from the device, as well as the speed at which they are moving. Particles moving toward the device will have a higher frequency and particles moving away from the device have a lower frequency. This

difference in frequencies is called the Doppler effect, and it allows the ADCP to calculate the velocity of the water along the path of a sound wave (Nortek 2023). A single ADCP beam can only sense the motion of particles that are moving parallel to the beam (i.e., one-dimensional velocity). However, by using multiple beams of sound in different directions, multi-beam ADCPs can measure particles moving in three-dimensional space (i.e., speed and direction) and at different depths (called bins) in the water column.

4.1.1 Low velocity threshold

While the lower limit of velocity detection can vary depending on site-specific conditions, ADCPs are typically not used to measure discharge in areas where velocities are less than approximately 0.3 feet (ft) per second (fps) (Mueller and Wagner 2009).

4.1.2 Homogeneous flow assumption

An ADCP assumes the flow field being measured is homogenous, meaning the particles in each depth cell (bin) are generally moving in the same direction. If the flow field is non-homogenous, errors or data gaps may result when computing velocity components from multiple beams that are receiving backscatter from particles moving in different directions. Multidirectional flows caused by density currents are common in tidally affected areas and have also been observed in freshwater environments where significant temperature gradients create density currents (Garcia et al. 2007).

4.1.3 Interference zone and bottom tracking

ADCP beams are shaped like cones which widen with increasing depth. Acoustic signals reflecting off particles are relatively weak and travel back to the ADCP along the centerline of the cone. However, reflections off hard surfaces (e.g., river or reservoir bottoms) are much stronger and introduce errors in the velocity calculations as some of the acoustic signal travels back to the ADCP along the sides of the cone. Therefore, ADCPs ignore data collected from the portion of the water column near the river or reservoir bottom. This is called the sidelobe interference layer. The depth of this layer is based on the angle of the ADCPs transducer heads and can also vary depending on the hardness of the bottom surface, but typically covers the bottom 6 to 13 percent of the water column (Nortek 2023).

ADCPs also track the bottom of the water column when measuring velocities to determine the overall depth of each data ensemble. A data ensemble is a single profile of the water velocity through the water column consisting of multiple stacked bins (i.e., each bin represents a single depth cell). If the individual transducer beams hit solid surfaces at different depths (for example, lakebed and submerged trees), the ADCP will only calculate velocity for bins that it can resolve. As a result, in addition to the sidelobe interference layer, additional data gaps may occur for bins near the bottom of the transect due to an inconsistent bottom profile. In this case, the ADCP will only calculate velocities for bins that can be resolved based on moving particles (i.e., higher in the water column).

4.1.4 Temperature effects

ADCPs use the speed of sound traveling through the water column to determine the distance to each depth cell (or bin). Sound speed is affected by water temperature, salinity, and depth. Water temperature is the most important of these three variables in calculating sound speed in water (sound speed increases with increasing water temperature and vice versa). As a result, presence of thermal stratification in the water column affects sound speed which in turn affects velocity measurements. For example, a difference of five degrees Celsius will cause a two percent bias error in the measured discharge (Oberg et al. 2005).

4.2 Field Data Collection

Velocity profiles were measured in the Whitewater River cove during three separate field visits on June 12 & 13, August 10 & 11, and September 20 & 21, 2023. Field work was conducted in parallel with regularly scheduled water quality monitoring in the Whitewater River cove in support of Task 2 of the Water Resources Study. Due to varying water depths along the transects, two different ADCPs were used; a deep-water ADCP and a shallow-water ADCP. Instrumentation and specifications for each are described in the following sections.

4.2.1 Instrumentation

4.2.1.1 Deep-water ADCP

The ADCP used for deep-water measurements in the Whitewater River cove was a Teledyne[©] RD Instruments, Inc. (Teledyne RDI) Workhorse Sentinel ADCP (300kHz) (Sentinel); this

FDS

model is ideally suited for a wide variety of applications (e.g., seafloor monitoring, wave data collection, vessel-mounted, buoy-mounted etc.). 1 It has a low-frequency, four-beam convex configuration (see Figure 4-1), a standard depth rating of 200 meters, and can be deployed upward or downward looking to measure flow velocities in the water column. The signal processing delivers low-noise data, resulting in high resolution data and minimal power consumption; Table 4-1 provides relevant specifications for the Sentinel.

4.2.1.2 Shallow-water ADCP

The ADCP used for shallow-water measurements in the Whitewater River cove was a Teledyne RDI RiverRay ADCP (RiverRay). The RiverRay is primarily for riverine applications and can sample continuously from bank to bank from rivers as shallow as 0.4 meters to rivers as deep as 40 meters.² The trimaran float (designed by OceanScience[©] specifically for use with this ADCP) provides reduced drag and less disturbance in shallow waters. A photo of the RiverRay is included on Figure 4-3 and Table 4-2 provides relevant specifications for the RiverRay ADCP.

Figure 4-2. Photo of Teledyne RDI RiverRay ADCP

4.2.2 Data Collection Methods

Proper field procedures are critical to obtaining high quality discharge measurements using ADCPs. For all transects, the ADCP was mounted to a flotation device and attached to a lead line which was held parallel to the boat as the boat motored along the transects. The deep-water ADCP (Sentinel) was mounted to a flotation device retrofitted with sections of high-density foam attached to the bottom and back of the float for additional vertical stability and to reduce backward tilt of the instrument as it was pulled through the water (Figure 4-3). The shallow-water (RiverRay) ADCP was mounted to a trimaran platform (Figure 4-4). Previous studies have shown velocity and discharge measurement errors are directly proportional to the speed of the boat; average boat speed during transect measurements should be less than or equal to the average water speed if possible (Mueller and Wagner 2009), therefore, very slow boat speeds were maintained during field measurements.

Operational data were obtained from Duke Energy for dates of flow data collection. Project operations data information is listed in Table 4-3 and includes pumping, generation, and reservoir elevation for Bad Creek Reservoir and Lake Jocassee. Table 4-3 also provides ADCP measurement details during field data collection.

4.2.3 Data Collection Challenges

There are many well-documented data collection challenges when measuring flows with an ADCP in the field; some of these were listed in Section 4.1 associated with ADCP assumptions. The U.S. Geological Survey (USGS) recommends the following guidelines for properly measuring flow velocities with an ADCP (Mueller and Wagner 2009).

- The cross section of a stream should be within a straight reach, and streamlines are parallel to each other. Flow should be relatively uniform and free of eddies, slack water, and excessive turbulence (Rantz et al. 1982).
- Desirable measurement sections should be roughly parabolic, trapezoidal, or rectangular. Asymmetric channel geometries should be avoided, if possible (Simpson 2002), as should cross sections with abrupt changes in channel bottom slope.
- The streambed cross section should be as uniform as possible and free from debris and vegetation or plant growth.
- Depth at the measurement site should allow for the measurement of velocity in two or more depth cells at the start and stop points near the left and right edges of the measurement section.
- Measurement sections with mean velocities less than 0.3 fps should be avoided if an alternative measurement location is available (Oberg et al. 2005). If maintaining a slow boat speed is not possible, maintain the slowest speed that allows smooth boat operation. (Additional transects may be needed to average turbulence and instrument noise.)
- Sites with non-uniform flow lines should be avoided. This condition is often indicative of non-homogenous flow, which is a condition that violates one of the assumptions required for accurate ADCP velocity and discharge measurements.

Several of the data collection challenges listed above are relevant to Lake Jocassee measurements. Additionally, turbidity in the water column and temperature affect measurements in the lake. Lake Jocassee is a very clear, oligotrophic reservoir with low concentrations of nutrients and thus, relatively sparse growth of algae and other organisms. Chlorophyll a concentrations collected in the Whitewater River cove are typically in the upper 105 ft of the water column (i.e., from full pond [1,110 ft msl] down to approximately 1,005 ft msl) with sporadic (both spatial and temporal) concentrations deeper than 105 ft. This is likely a combination light penetration through the upper layers of the water column and the depth of the thermocline (below which water temperatures are cooler and dissolved oxygen concentrations are lower compared to the upper surface layers). As a result, zooplankton densities are also likely to be relatively sparse (as they use plankton as a primary food source) and mostly present in the

upper 105 ft of the water column. Lake Jocassee also has very low turbidity levels, typically less than 1.0 NTU³. Because ADCP technology measures particles moving in the water column, lack thereof results in an insufficient amount of acoustic energy reflected back to the transducer to allow the ADCP to measure the Doppler shift; thus resulting in data gaps, particularly in deeper areas that are devoid of both organisms and turbidity.

Additionally, the Whitewater River arm of Lake Jocassee is deep with most of the flow on the downstream side of the submerged weir contained in the upper portion of the water column. Deeper areas have very slow-moving water (less than 0.3 fps) and coupled with areas that may have non-homogenous flow (due to density currents near the thermocline) and/or very few particles to measure, therefore, it is reasonable to expect bins where the velocity cannot be resolved.

Finally, the area that was flooded to form Lake Jocassee was not cleared prior to filling, therefore, it is reasonable to expect submerged trees that are either still standing and/or have fallen but have not yet decomposed. As a result, bottom tracking is challenging in some areas as the ADCP beams backscatter off hard objects at different elevations at the same location. This causes decorrelation of the acoustic pulse and results in bins where the velocity cannot be computed.

Erroneous and/or inconsistent data values at lower depths attributed to challenging field conditions in the Whitewater River cove are discussed in Section 4.3.

4.3 Post-Processing and Model Verification

WinRiver II is a real-time discharge data collection software developed by Teledyne RDI for collecting and processing data gathered by an ADCP. To make accurate comparisons between measured and modeled data, ADCP data was post processed using WinRiver II. The number of horizontal readings per transect is provided in Table 4-3 (i.e., ensembles per ft). The density of these readings or ensembles (each of which is comprised of stacked "bins" as described in Section 4.1), ranged from 1.1 to 4.4 ensembles/ft. The CFD model mesh used for this study was 20-ft x 20-ft x 10-ft (X,Y,Z directions). To match the CFD model output, the ADCP data was

³ Nephelometric turbidity unit

horizontally averaged into 20-ft ensembles. WinRiver II does not have a method for averaging data in the vertical direction.

4.4 Modeling Assumptions

The CFD model is a numerical approximation of the hydraulics in the Whitewater River arm of Lake Jocassee. Because of the slow-moving nature of the flow patterns in the Whitewater River arm, the model mesh size (i.e., 20-ft x 20-ft x 10-ft) is appropriate to model the velocity magnitudes and direction and mixing / recirculation patterns associated with existing and proposed Bad Creek Project operations.

Inflows to the model were assumed to be constant and uniform in the horizontal and vertical directions. In reality, properties of the water such as temperature (which affects the density of water in thermally stratified waterbodies like Lake Jocassee) play a role in the distribution of flow across a given transect; however, only hydraulics were modeled with the CFD model. Potential hydraulic effects of temperature gradients, flow bulking and buoyancy, or wind-driven vertical mixing were not included. Given these assumptions and model limitations, it is not expected that the CFD model results will exactly replicate real-world conditions within the model domain. However, the CFD model configuration is suitable for purposes of determining potential Project-related operational impacts to flow patterns and vertical mixing in the Whitewater River arm of Lake Jocassee.

5 Verification Results

As described above, two different ADCPs were used to collect velocity data in the Whitewater River arm as part of the CFD model verification effort. The Sentinel and RiverRay transducer heads are mounted with a 20-degree and 30-degree offset from vertical, respectively. This equates to a minimum sidelobe interference zone along the bottom of the reservoir of 5 percent and 8 percent of total depth, respectively. This interference zone is visible as a well-defined band of varying vertical thickness with no data along the bottom of each transect shown on Figure 5-1 through Figure 5-4 (all figures displaying transects are oriented looking in the upstream direction).

As discussed in Section 4.1, there are several assumptions and limitations associated with ADCP data collection. When data collection occurs outside of these assumptions and limitations, erroneous data can occur in the transects, generally in the form of blank cells or artificially high velocity measurements. Data resolution errors in velocity measurements will show up as velocity spikes when compared with the neighboring valid velocity measurements. Mueller and Wagner describe five causes for erroneous or invalid ensembles (Mueller and Wagner 2009):

- 1 Invalid bottom tracking, which would provide no boat reference from which to compute the velocity,
- 2 Decorrelation of the acoustic pulse (from turbulence, high shear, submerged debris, or fish) which would not permit an accurate measurement of the Doppler shift,
- 3 Low backscatter, which results in an insufficient amount of acoustic energy reflected back to the ADCP to measure the Doppler shift,
- 4 The blocking of acoustic pulses by air entrainment, and
- 5 User-specified data quality criteria.

Velocities depicted on Figure 5-1 were measured along Transect 1 which is the furthest upstream transect near water quality monitoring station 564.1. Velocity data shown on Figure 5-1 were collected with the Project in pumping mode to evaluate velocity magnitudes and flow patterns in the area most affected by pumping operations (i.e., near the Project's inlet/outlet structure). Velocities shown on Figure 5-1 are generally moving in the upstream direction towards the Project inlet/outlet structure. The overall measured velocity magnitude is < 0.5 fps from top to bottom (upper panel on Figure 5-1) indicating flows in this area are generally slow moving, but well mixed throughout the water column, which also matches the CFD model results (lower panel on Figure 5-1). Both historic and current water quality profiles at this location also indicate the water column in this area is well-mixed due to Project operations.

Velocities shown on Figure 5-2 were measured across the top of the submerged weir (Transect 2) with the Project in generation mode. The maximum depth along Transect 2 is 53 ft; it is the shallowest of the ADCP transects which range from 53 to 234 ft deep. Due to the smaller cross-sectional area for discharged water to pass through, the area across the top of the weir is also well mixed and exhibits higher velocities compared to the other transects. Maximum measured

velocities across the top of the weir with the Project in generation mode were close to 1.0 fps while the majority of Transect 2 had velocities < 0.5 fps (upper panel on Figure 5-2). The CFD model results for Transect 2 were similar to the measured data and also exhibited areas with higher velocities up to approximately 0.7 fps (lower panel on Figure 5-2).

Transects 1 and 2 exhibited complete datasets with no obvious invalid cell measurements or erroneous data, as many of the challenges and limitations associated with ADCP data collection (described above) were not a factor at these two transects.

Figure 5-3 and Figure 5-4 show results of the two downstream transects (Transects 3 and 4). These transects are deeper and the velocities are slower at these two locations compared to Transects 1 and 2. There are numerous invalid ensembles and velocity spikes for both of these transects, indicated by white cells (no data) and artificially high velocities (yellow/orange/red colors at depth or near invalid cells). A review of the ADCP bottom tracking data shows continuous black lines along the bottom of each transect indicating that there were no issues with bottom tracking. Air entrainment (typically due to turbulence) was also not an issue at Transects 3 and 4 and no specific user quality criteria were used in the measurements. This means the invalid ensembles displayed on Figure 5-3 and Figure 5-4 were likely the result of decorrelation of the acoustic pulse and/or low backscatter due to lack of moving particles in the water column (particularly at deeper depths).

Transect 3 (Figure 5-3) is located between the submerged weir and water quality monitoring location 564.0. This location has slightly elevated velocities near the surface which is carry-over from the higher velocities across the top of the submerged weir. Most of the velocities at this location are generally < 0.5 fps which is consistent with the CFD model results. There are several areas along the left-hand side of Figure 5-3 with missing or erroneous data at depth. The first is a series of blank bins around an erroneously high velocity spike (i.e., >1.0 fps) to the left of ensemble 3854. The second is an area of missing data just to the right of ensemble 3854. And the third is an area of missing area approximately halfway between ensembles 3854 and 2625.

As previously discussed in Section 4.2.3, Lake Jocassee has very low turbidity and sparse growth of algae and other organisms. These two factors increase the likelihood of low backscatter, especially at depth. Additionally, because trees and other debris were not cleared before Lake Jocassee was filled, there are likely many areas where trees are still standing, which can cause

decorrelation of the acoustic pulse. The invalid cells farthest to the left of Figure 5-3 appear to be caused by either standing trees and/or low backscatter. The bottom tracking is continuous at the second area, however there is an abrupt change in bottom elevation likely caused by submerged debris. The third location (to the right) is in the deepest part of the transect and the blank cells there are likely caused by low backscatter.

Transect 4 (Figure 5-4) is located just upstream of the confluence of the Whitewater River arm and Thompson River arm. It is the deepest of the four transects (maximum 234 ft) and velocities are very low (<0.50 fps) from the surface to the bottom. There are numerous areas along Transect 4 with either blank cells and/or erroneous high velocities at depth. The combination of low back scatter and submerged debris interrupting the acoustic pulse are feasible explanations for these areas of invalid data; most of the invalid data points are below depths of 100 feet, where there is little turbidity or organic growth present to reflect the acoustic energy back to the ADCP.

While Transects 3 and 4 exhibit some blank cells and erroneous data, this is to be expected when measuring velocities in deep, clear water with very low velocities (i.e., < 0.3 fps). Knowing that data collection would be a challenge at these two locations, extra time was taken in the field to collect a higher density of data ensembles, including hovering in place over areas where data gaps occurred in an attempt to minimize those gaps. Most of the data ensembles at these two locations are complete and a comparison of measured velocities in the upper panels of Figure 5-3 and Figure 5-4 is consistent with the CFD model results shown in the lower panels of these two figures.

Figure 5-4. Measured Velocity (top) vs Modeled Velocity (bottom) Transect 4 (Upstream of Thompson River-Whitewater River Confluence)

6 Conclusions

ADCP velocity measurements at the four transects located in the Whitewater River arm of Lake Jocassee generally corroborate the CFD model results at these locations. Velocity magnitudes and directions and overall flow patterns are consistent with CFD model results which show a mixed water column on the upstream side of the submerged weir (Transect 1), and area of slightly higher velocities across the top of the submerged weir (Transect 2) and deeper, slower moving water (i.e., < 0.50 fps) towards the Whitewater River arm / Thompson River arm confluence.

As discussed in Section 4.1, there are several assumptions and limitations associated with ADCP data collection that can make velocity data resolution challenging, especially in deep, clear, slow-moving water such as the Whitewater River arm of Lake Jocassee. In particular, the lack of moving particles in the lower portions of the water column, coupled with very slow-moving water (i.e., <0.30 fps) in many areas resulted in data gaps and erroneous velocity spikes. Even with these challenges, a robust velocity dataset was collected at each of the four transect locations and results are consistent with the CFD model results in both pumping and generation mode.

Overall, velocities predicted with the CFD model compare well with measured velocities across each transect. Modeled velocities are generally within 0.1-0.3 fps of valid measured velocities and accurately represent actual flow dynamics. This study is considered appropriate and sufficient to provide confidence in the CFD model results used to carry out Task 3 of the Water Resources Study.

1 Project Introduction and Background

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir and Lake Jocassee, which is licensed as part of the Keowee-Toxaway Hydroelectric Project (FERC Project No. 2503), as the lower reservoir.

The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977, and expires July 31, 2027. The license has been subsequently and substantively amended, with the most recent amendment on August 6, 2018 for authorization to upgrade and rehabilitate the four pump-turbines in the powerhouse and increase the Authorized Installed and Maximum Hydraulic capacities for the Project.¹

Given the need for additional significant energy storage and renewable energy generation across Duke Energy's service territories over the Project's new 40 to 50-year license term, Duke Energy is evaluating opportunities to add pumping and generating capacity at the Project. Additional energy storage and generation capacity would be developed by constructing a new power complex (including a new underground powerhouse) adjacent to the existing Bad Creek powerhouse. Therefore, construction of the 1,400-megawatt Bad Creek II Power Complex (Bad Creek II Complex or Bad Creek II) is an alternative relicensing proposal presently being evaluated by Duke Energy.

During the feasibility study phase for Bad Creek II, a three-dimensional (3-D) computational fluid dynamics (CFD) model was developed by HDR Engineering, Inc (HDR) to evaluate impacts under combined operation of the existing and proposed projects on water velocities in the Whitewater River cove (WWRC) of Lake Jocassee downstream of the inlet/outlet (I/O) structures. Results from the CFD feasibility modeling study are presented in the Feasibility Study Report as Volume 5 (*Bad Creek II Power Complex Feasibility Study Lower Reservoir CFD Flow Modeling Report*; HDR 2022). This report was also included in the Revised Study Plan

¹ Duke Energy Carolinas LLC, 164 FERC ¶ 62,066 (2018)

submitted to FERC on December 5, 2022. During studies for relicensing in 2023, a second CFD model was developed under Task 3 of the Water Resources Study (*Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse*) to determine flow patterns and extent of vertical mixing in the WWRC due to the addition of a second powerhouse. Findings from that study were provided in Appendix A of the Initial Study Report (ISR) submitted to the Commission on January 4, 2024 (Duke Energy 2024).

After filing the ISR, Duke Energy provided updated hydraulic capacities, provided by the preferred Original Equipment Manufacturer, for proposed variable speed pump-turbines for Bad Creek II. Based on this information, additional CFD modeling was conducted using the updated proposed hydraulic capacities. This report includes the results of updated CFD modeling and is being provided as an addendum to the Task 3 study report for the Bad Creek relicensing Water Resources Study.

2 Objectives

Increased hydraulic capacities associated with Bad Creek II could affect flow patterns and velocities in the WWRC near the I/O structures. The purpose of this addendum is to provide results of additional CFD model runs carried out to incorporate updated hydraulic capacities associated with Bad Creek II that were not available during original CFD modeling. Updated generating capacity resulted in similar flows as originally estimated (i.e., less than 2 percent difference), so this report's focus is to present the effects of updated pumping capacities on WWRC flows.

3 Study Area

The study area for this assessment includes the area of the WWRC from the immediate vicinity of the Project's existing and proposed I/O structures to the upstream end of the submerged weir (see Figure 3-1; blue rectangle defines study area). Previous CFD modeling results carried out under Task 3 of the Water Resources Study showed the submerged weir limits effects of operations downstream of the weir, therefore, updated modeling focused on the area upstream of the weir only.

Figure 3-1. CFD Updated Modeling Study Area: Whitewater River Cove

4 Hydraulic Capacities

Existing hydraulic capacities for the Bad Creek Project are included in Table 1. This table shows as-constructed and previously licensed Project capacities and upgraded unit capacities (as amended). On April 23, 2018, Duke Energy filed a Non-Capacity License Amendment Application to upgrade and refurbish the four Francis-type pump-turbines in the powerhouse, replace existing runners with Francis-type pump-turbine runners, and rehabilitate and/or upgrade

the remaining components of the pump-turbine runners at the Bad Creek Project. Authorized installed and maximum hydraulic capacities for the Project were increased to 1,400 megawatts (based upon the definition provided by 18 CFR §11.1[i])² and 19,760 cubic feet per second (cfs), respectively. The upgrades were approved by FERC in an amendment order dated August 6, 2018 and modifications for Units 1 – 3 were completed by March 2023 and Unit 4 was completed in February 2024. The upgraded Project is the baseline for the relicensing and upgraded unit capacities were used for (CFD) modeling existing conditions.

Hydraulic capacities at the Project under previously licensed and upgraded (i.e., as amended in 2018) conditions are included in Table 4-1. Results of CFD modeling incorporating upgraded capacities are presented as existing conditions in Volume 5 of the Feasibility Study Report (HDR 2022) upstream of the submerged weir and in the CFD Task 3 report in the ISR (Duke Energy 2024) for downstream of the submerged weir.

Table 4-1. As-Constructed (Original) and Upgraded (Amended) Project Hydraulic Capacities

Bad Creek (Existing Project)						
Unit	Generation		Pumping			
	Original (cfs)	Upgraded/Existing (cfs)	Original (cfs)	Upgraded/Existing (cfs)		
Unit 1	4,000	4,940	3,690	4,060		
Unit 2	4,000	4,940	3,690	4,060		
Unit 3	4,000	4,940	3,690	4,060		
Unit 4	4,000	4,940	3,690	4,060		
Total	16,000	19,760	14,760	16,240		

Prior CFD modeling for proposed conditions followed the assumption that Bad Creek II would be constructed with four reversible pump-turbine units similar to the configuration at the existing Project with the same generation and pumping capacities (see Table 4-1). However, during recent (2023) optimization studies for the Bad Creek II Complex, variable speed pump-turbine

² Authorized installed capacity means the lesser of the ratings of the generator or turbine units. The rating of a generator is the product of the continuous-load capacity rating of the generator in kilovolt-amperes (kVA) and the system power factor in kW/kVA. If the licensee or exemptee does not know its power factor, a factor of 1.0 kW/kVA will be used. The rating of a turbine is the product of the turbine's capacity in horsepower (hp) at best gate (maximum efficiency point) opening under the manufacturer's rated head times a conversion factor of 0.75 kW/hp. If the generator or turbine installed has a rating different from that authorized in the license or exemption, or the installed generator is rewound or otherwise modified to change its rating, or the turbine is modified to change its rating, the licensee or exemptee must apply to the Commission to amend its authorized installed capacity to reflect the change.

units were selected as the chosen configuration (instead of fixed-speed), which resulted in an increase in proposed hydraulic capacities for Bad Creek II as show in Table 4-2.

Table 4-2. Updated Bad Creek II Hydraulic Capacities

Bad Creek II					
	Generati	on	Pumping		
Unit	Previously Proposed (cfs)	Updated Proposed (2023) (cfs)	Previously Proposed (cfs)	Updated Proposed (2023) (cfs)	
Unit 1	4,940	5,000	4,060	4,890	
Unit 2	4,940	5,000	4,060	4,890	
Unit 3	4,940	5,000	4,060	4,890	
Unit 4	4,940	5,000	4,060	4,890	
Total	19,760	20,000	16,240	19,560	

In consideration of the recent 2023 updated capacities, total generation capacity with both projects operating would be 39,760 cfs (19,760 + 20,0000 cfs). Modeled (CFD) versus updated generation capacity is similar (39,200 cfs vs. 39,760 cfs), resulting in a less than 2 percent difference. It is anticipated this difference would not substantially affect existing results (as reported in the ISR); therefore, generation capacity was not assessed further.

Total pumping capacity (with both projects) would be 35,800 cfs (16,240 + 19,560 cfs), resulting in a 9 percent increase (i.e., 32,720 cfs vs. 35,800 cfs); therefore, additional model runs were performed under proposed configurations for pumping operations under full pond and minimum normal pond elevations in Lake Jocassee.

5 Lake Jocassee Lake Levels

The lower reservoir has a licensed operating band between 1,110 ft msl (full pond) and 1,080 (minimum pond or maximum drawdown). Results under full pond and maximum drawdown provide potential upper and lower limits of hydraulic effects of Bad Creek II operations. Figure 5-1 provides an exceedance plot of the Lake Jocassee pond level from 1975 to 2020. This plot shows the percentage of time the reservoir is at or above a given elevation. Lake Jocassee operates within 5 ft of the full pond elevation of 1,110 ft roughly 50 percent of the time, and in the 45-year period of record Lake Jocassee has never reached the maximum drawdown elevation.

FDS

For this evaluation, unit operations in pumping mode were simulated with the existing and proposed structures at reservoir levels 1,110 ft msl, 1,096 ft msl, and 1,080 ft msl. The elevation of 1,096 ft msl was selected as an intermediate lake elevation operating scenario because it is roughly halfway between full pond and maximum drawdown, and 1,096 ft msl is the elevation below which fish entrainment becomes elevated at Bad Creek (historically, reservoir elevations were lower than 1,096 ft msl approximately 22 percent of the time).

Figure 5-1. Lake Jocassee Pond Level Exceedance

6 Proposed Tunnel Configuration

The Bad Creek II I/O structure will be located in a portal area adjacent to the existing Bad Creek I/O structure (upstream of the existing I/O structure). The proposed location of the new I/O structure portal for Bad Creek II is shown on Figure 6-1.

A schematic of the proposed tunnels extending from the underground powerhouse to the western bank of the WWRC is shown below (Figure 6-2). The proposed I/O structure will be approximately 150 ft wide, 20 ft deep, and 95 ft tall. The location of the structure was selected to

minimize the length of the water conveyance tunnel, permit access, and reduce construction-related environmental impacts to the Whitewater River arm of Lake Jocassee. Two tailrace tunnels extending from the underground powerhouse will penetrate the I/O structure at invert elevation 1,012 ft msl. The two tailrace tunnels are divided into a left and right chamber as the tunnels approach the portal opening. Each tunnel has a diameter of 31 ft and the chambers at the outlet are approximately 38 ft tall by 17.5 ft wide. Flows through the center two chambers (Tunnel 1 Right and Tunnel 2 Left) create higher velocities at the tunnel entrances when compared to the outer two chambers (Tunnel 1 Left and Tunnel 2 Right) which is discussed further in Section 8.

Figure 6-1. Proposed Bad Creek II Lower Reservoir I/O Structure Portal Adjacent to Existing I/O Structure Portal

Note: The left and right tunnel naming convention is based on the direction of flow from the tunnel into Lake Jocassee.

Figure 6-2. Proposed Bad Creek II Powerhouse Tunnel Configuration

7 Methods

7.1 Feasibility CFD Model

As noted in Section 1, two CFD models were previously developed by HDR for the Bad Creek and Bad Creek II projects. The first CFD model was built for the feasibility study (HDR 2022) with the goal of identifying flow velocities and patterns under generation and pumping scenarios with various water level elevations in the WWRC near the I/O structure (upstream of the submerged weir) and to assess the potential for erosion along the opposite (east) shoreline due to increased generation flows from the combined powerhouses. This feasibility model was built with a computational mesh block resolution of 4-ft by 4-ft (length by width by height). Background, methods, and findings of this study are provided in the Bad Creek II Power Complex Feasibility Study Lower Reservoir CFD Flow Modeling Report (HDR 2022) and was also provided in the Revised Study Plan as Appendix I.

7.2 Relicensing CFD Model

The second CFD model was developed for the relicensing study to determine velocity effects and vertical mixing in the WWRC due to operation of a second powerhouse and considering the area downstream of the submerged weir. Inflows to the model were assumed to be constant and

uniform in the horizontal and vertical directions approaching the submerged weir. The long-term average flowrate from the Thompson River arm was also included in the model to incorporate flows downstream of the weir. Because this model incorporated a larger (922 acres) and deeper area of Lake Jocassee (with very slow water circulation), a coarser model mesh was appropriate to meet the objectives and a computational mesh block of 20-ft by 20-ft by 10-ft (length by width by height) was used. Background, methods, and findings of this study were included in the ISR as Appendix A, Attachment 3 (Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse) (Duke Energy 2024).

7.3 Updated CFD Model

As described above, recent optimization studies have proposed variable-speed turbines for the Bad Creek II Complex, which will result in increased hydraulic capacities compared to those initially proposed and modeled. Because the objective of this report is to assess near-field hydraulics and changes in velocity in the vicinity of the I/O structures due to increased pumping capacity associated with recently proposed variable speed turbines, the Feasibility CFD Model (described in Section 7.1) was considered the most appropriate model (as opposed to the Relicensing CFD Model) to carry out this evaluation. Model description, geometry, evaluation criteria, and mesh development are described in detail in HDR (2022) and are therefore not provided here.

Modeling with variable speed units did not appreciably increase generation flows, however the effects of increased pumping hydraulic capacity did result in a measurable change (i.e., 9 percent), therefore only updated pumping scenarios are discussed in Section 8. Updated generation flows resulted in a flow difference of less than 2 percent, therefore, the results presented in the original Feasibility CFD Model report (HDR 2022) were not revised.

8 Results

8.1 Existing Pumping Velocity Profiles

Existing pumping conditions (16,240 cfs) at cross-section elevations (i.e., model slices) representing full pond (1,100 ft msl), intermediate (1,096 ft msl), and maximum drawdown

(1,080 ft msl) are shown on Figure 8-1, Figure 8-2, and Figure 8-3, respectively. All estimated velocities are included in the attached results table in Attachment 1.

Under existing pumping conditions at the full pond elevation (Figure 8-1), depth-averaged velocities³ approaching the I/O structure (i.e., approach velocities) are 1.8 fps approximately 100 ft from the I/O structure with a maximum velocity of 2.1 fps. Maximum velocities in the water column near the face of the I/O structure vary based on tunnel position and the hydrostatic pressure acting on tunnel flows and range from 5.5 fps to 6.2 fps.⁴

Under existing pumping conditions at the intermediate pond elevation (Figure 8-2), depth-averaged approach velocities are 2.2 fps approximately 100 ft from the I/O structure with a maximum velocity of 2.5 fps. Maximum velocities near the face of the I/O structure range from 7.2 fps to 7.7 fps.

Under existing pumping conditions at the minimum pond elevation (Figure 8-3), depth-averaged approach velocities are 4.6 fps approximately 100 ft from the I/O structure with a maximum velocity of 5.2 fps. Maximum velocities near the face of the I/O structure range from 7.9 fps to 8.4 fps.

Under existing pumping conditions, the maximum velocity inside the I/O tunnel chambers near the structure face is approximately 13.3 fps and approximately 23 fps in the tailrace tunnel based on the 31-ft-diameter tunnel and given flowrates.

The width of the WWRC (see Figure 3-1) at the existing I/O structure is approximately 1,110 ft and the extent of velocity effects (as shown on Figure 8-3) extend approximately 230 ft from the I/O structure into the WWRC at the minimum pond elevation.

³ It is noteworthy that bathymetry of the lake bottom impacts flows as they approach the tunnel openings.

⁴ Trashracks on the I/O structure are not considered, therefore velocities at the face of the tunnels would be higher than shown here.

Figure 8-1. Existing Bad Creek I/O Pumping at 1,110 ft msl

Figure 8-2. Existing Bad Creek I/O Pumping at 1,096 ft msl

Figure 8-3. Existing Bad Creek I/O Pumping at 1,080 ft msl

8.2 Updated Proposed Pumping Velocity Profiles

As shown on Figure 8-4 through Figure 8-6, the updated increased pumping capacity at Bad Creek II results in higher velocities in the WWRC in the vicinity of the proposed I/O structure when compared to existing velocities at the Bad Creek I/O structure (Figure 8-1 through Figure 8-3). All velocities are included in the attached results table in Attachment 1.

Under updated pumping conditions at the full pond elevation (Figure 8-4), depth-averaged approach velocities for the proposed I/O structure are 1.7 fps approximately 100 ft from the I/O structure with a maximum velocity of 2.0 fps. Maximum velocities in the water column near the face of the I/O structure vary based on tunnel position and hydrostatic pressure and range from 9.6 fps to 10.1 fps.

Under updated pumping conditions at the intermediate pond elevation (Figure 8-5), depth-averaged approach velocities are 2.5 fps approximately 100 ft from the I/O structure with a maximum velocity of 3.1 fps. Maximum velocities near the face of the I/O structure range from 9.2 fps to 9.7 fps.

Under updated pumping conditions at the minimum pond elevation (Figure 8-6), depth-averaged approach velocities are 4.5 fps approximately 100 ft from the I/O structure with a maximum velocity of 8.3 fps. Maximum velocities near the face of the I/O structure range from 7.4 fps to 10.9 fps.

Under updated pumping conditions, the maximum velocity inside the I/O tunnel chambers near the structure face is approximately 16 fps and approximately 28 fps in the tailrace tunnel based on the 31-ft diameter-tunnel and given flowrate.

The width of the WWRC (see Figure 3-1) at the proposed I/O structure is approximately 675 ft and the extent of velocity effects (as shown on Figure 8-6) extend approximately 400 ft from the I/O structure into the WWRC at the minimum pond elevation.

Figure 8-4. Proposed Bad Creek II I/O Updated Pumping at 1,110 ft msl

Figure 8-5. Proposed Bad Creek II I/O Updated Pumping at 1,096 ft msl

Figure 8-6. Proposed Bad Creek II I/O Updated Pumping at 1,080 ft msl

8.3 Surface Velocities

Plan view flow patterns and velocity vectors at the three reservoir levels (i.e., full, intermediate, and minimum pond) are presented on Figure 8-7, Figure 8-9, and Figure 8-9, respectively. Areas of recirculation occur near the west and east banks under both full pond and minimum pond scenarios, and, similar to the profile figures, velocities increase as reservoir levels decrease and with increased proximity to the proposed I/O structure, as indicated by velocity vectors. Recirculation patterns in the vicinity of the proposed I/O structure under the minimum pond scenario are also indicated on Figure 8-9. These patterns are caused by flow splitting at the tunnel abutments and the restricted flow area near the I/O structure, resulting in increased velocities.

As the pond level decreases, the volume of water decreases and increases the strength of recirculation in the recirculation area. This effect results in concentrated flow through the center of the proposed I/O structure approach channel and center tunnels (Tunnel 1 Right, Tunnel 2 Left) and is more pronounced as the pond level decreases.

Accelerated flows across the weir in the direction of the I/O structure are more pronounced at minimum pond (Figure 8-9). As water is pulled upstream through the WWRC during pumping,

FD3

flows are spread evenly across the submerged weir before converging into a main center channel in the cove, with localized eddies of slower moving water (i.e., recirculation) on both sides of the main flow path.

Figure 8-7. Proposed Bad Creek II I/O Updated Pumping Plan View at Elevation 1,110 ft msl

Figure 8-8. Proposed Bad Creek II I/O Updated Pumping Plan View at Elevation 1,096 ft msl

Figure 8-9. Proposed Bad Creek II I/O Updated Pumping Plan View at Elevation 1,080 ft msl

Surface velocity contours are shown on Figure 8-10 and Figure 8-11 for existing conditions⁵ and Figure 8-12 and Figure 8-14 for proposed updated pumping conditions under full, intermediate, and minimum pond levels.

Under existing pumping conditions and full pond levels, surface velocities do not exceed 2.0 fps in the WWRC and are on average below 1.0 fps. At minimum pond, existing maximum surface velocities across the weir could reach 3.0 fps and up to 5.0 fps directly in front of the existing I/O structure.

Under full pond conditions for proposed updated pumping operations, velocities are very similar to existing conditions with maximum velocities of 1.5 fps near the existing and proposed I/O structures. Under proposed updated pumping at the minimum pond level, surface velocities could reach 10.0 fps near the proposed I/O structure (see Figure 8-14 and Figure 8-9); however, these higher velocities are localized and constrained within the small area adjacent to the I/O structure in a recessed alcove. As part of Bad Creek II construction, expansion of the submerged weir (in the downstream direction) is being considered; maximum velocities over the proposed expanded weir are 3.5 fps, which are consistent with maximum velocities over the existing submerged weir.

As indicated above, surface velocities <u>under minimum pond</u> could reach 10.0 fps, which could have implications for non-motorized boats moving northward through WWRC, however, the high flows are constrained to the area immediately adjacent to the I/O structure within the recessed area of the shoreline where the proposed I/O will be constructed. Additionally, as shown on Figure 8-9, at minimum pond the area upstream of the proposed I/O is largely dewatered and therefore would not support boating activities regardless of Bad Creek II operations. It should be noted that Lake Jocassee has never been at the licensed maximum drawdown since its creation; maximum drawdown scenarios in this evaluation provide the most conservative hypothetical condition.

⁵ A surface velocity map was not generated for the existing intermediate pond level as this scenario was not evaluated as part of the feasibility study; however, it is expected that the results would be similar to Figure 8-13.

9 Conclusions

As expected, velocities in the WWRC under all operational scenarios increase with decreased reservoir elevations. As stated in Section 5, Lake Jocassee has never been at the licensed maximum drawdown since its creation and it is worth noting Bad Creek II would likely not operate at maximum hydraulic capacities in the unlikely event of a drawdown (licensed minimum pond level). Therefore, maximum drawdown scenarios with maximum pumping evaluated in this study provide the most conservative results.

As indicated in Section 8.3, surface velocities in the WWRC under minimum pond elevations could reach 10.0 fps, which may have implications for non-motorized boats moving through the WWRC near the Project. To support the relicensing effort, Duke Energy carried out a Whitewater River Cove Existing Recreational Use Evaluation with the goal of characterizing the existing recreational use of Whitewater River cove to inform Duke Energy on the level of boating use disruption that could occur in the cove during the Bad Creek II Complex construction.6 The final Existing Recreational Use Evaluation, which was developed in consultation with relicensing stakeholders, was filed with Initial Study Report in January 2024. Results of this study, which was carried out from Memorial Day through Labor Day in 2023, showed the majority of boats in Whitewater River cove were motorboats (83 percent), followed by personal watercraft (e.g., jet ski) (10 percent), kayaks (7 percent), and canoes (less than 1 percent); therefore, a minor percentage (<10%) of boaters using the WWRC do so in a nonmotorized boat. It is likely from a recreational boater safety perspective, boats would be able to navigate this area of the WWRC by keeping to the east side of the WWRC along the shore opposite the proposed I/O structure since the new I/O structure would be situated approximately 200 ft back from the existing shoreline in a recessed alcove (shown on Figure 6-1). It is important to note that at low reservoir elevations, the northern portion of the WWRC would be dewatered and therefore be inaccessible (depicted on Figure 8-9) as the reservoir bottom elevation in this area is higher than 1,080 ft msl. As a result, boating in this area of WWRC would largely be precluded by low lake levels, regardless of Bad Creek II operations. Duke Energy plans to carry out additional analyses and develop proposed guidelines for boater safety

⁶ Whitewater River cove will be closed to recreation during Bad Creek II construction (approximately 7 years) for public safety.

and recreational use under future operations in consultation with relicensing stakeholders; findings from that study will be included in the Updated Study Report.

1 Project Introduction and Background

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir and Lake Jocassee, which is licensed as part of the Keowee-Toxaway (KT) Hydroelectric Project (FERC Project No. 2503), as the lower reservoir.

The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977, and expiration date of July 31, 2027. The license has been subsequently and substantively amended, with the most recent amendment on August 6, 2018, for authorization to upgrade and rehabilitate the four pump-turbines in the powerhouse and increase the Authorized Installed and Maximum Hydraulic capacities for the Project. Duke Energy is pursuing a new license for the Project pursuant to the Commission's Integrated Licensing Process, as described at 18 Code of Federal Regulations (CFR) Part 5.

In accordance with 18 CFR §5.11 of the Commission's regulations, Duke Energy developed a Revised Study Plan (RSP) for the Project and proposed six studies for Project relicensing. The RSP was filed with the Commission and made available to stakeholders on December 5, 2022. FERC issued the Study Plan Determination on January 4, 2023, which approved the Water Resources Study in the RSP as proposed.

This study was conducted in consultation with the Water Resources Resource Committee (RC), Aquatic Resources RC, Operations RC, and other interested stakeholders. Copies of consultation records are included in Appendix A of the Updated Study Report. This report includes the findings for Task 4 (Water Exchange Rates and Lake Jocassee Reservoir Levels) of the Water Resources Study.

¹ Duke Energy Carolinas LLC, 164 FERC ¶ 62,066 (2018)

2 Study Goals and Objectives

Tasks carried out for the Bad Creek Water Resources Study have been consistent with the scope and level of effort described in the RSP filed with the Commission on December 5, 2022. This report is intended to provide sufficient information to support an analysis of the potential Project-related effects on water resources with clear nexus to the Project.

Operation of the proposed Bad Creek II Power Complex (Bad Creek II), which will add pumping and generating capacity to the Project, has the potential to affect the magnitude, rate, and frequency of water surface elevation changes² in downstream reservoirs. Therefore, the objective of this task is to update the existing Computerized Hydro Electric Operations Planning SoftwareTM (CHEOPS) model developed during KT Project relicensing to evaluate reservoir elevation effects associated with water exchange rates, magnitude, and duration between Bad Creek Reservoir and Lake Jocassee. In addition, potential impacts to Lake Keowee levels and fluctuations resulting from operation of Bad Creek II are presented.

3 Study Area

The study area for the modeling effort includes the Bad Creek Reservoir, Lake Jocassee (i.e., the lower reservoir), Lake Keowee (Figure 3-1), and to a lesser extent, the three downstream reservoirs owned and operated by the U.S. Army Corps of Engineers (USACE).

² Water levels would be required to conform to the existing requirements of the KT Project License and associated agreements. Additionally, the originally licensed operating band of the upper Bad Creek reservoir (i.e., 160 feet) is not proposed to be modified.

Figure 3-1. Study Area for CHEOPS Evaluation

4 Model Development

4.1 Model Overview

Duke Energy elected to use HDR's proprietary CHEOPS model to assess the effects of operations associated with the addition of Bad Creek II on the system's overall water exchange between the Bad Creek Reservoir and Lake Jocassee. CHEOPS is specifically designed to evaluate the effects of operational changes and physical modifications at multi-development hydroelectric projects. The model is a tool for evaluating a wide range of physical changes and operational constraints associated with relicensing and upgrading hydro facilities. One of the many strengths of the CHEOPS model is the degree of customization available to modelers; it can be tailored to meet the demands of the system being modeled. The CHEOPS program architecture provides a platform for investing project-specific features as defined by stakeholder interests.

CHEOPS utilizes daily flows, plant generating characteristics, and operating criteria of the system to simulate operations, allocate flow releases, and calculate energy production within the system. The model calculates headwater elevation, headlosses, net head, turbine discharge and spill, and power generation. CHEOPS is designed for long-term analysis of the effects of operational and physical changes made to the modeled hydroelectric system.

Modifications to the CHEOPS platform during KT relicensing to support the Savannah River (SR) CHEOPS Model included functionality enhancements enabling simulation of conditions (e.g., Duke Energy Low Inflow Protocol [LIP], and USACE Drought Contingency Plan [DCP]), which were developed during the KT Project relicensing process, as well as improved logic for upstream/downstream plant interactions, specifically with pumped storage plants in the system. The model was also enhanced to add wicket gate leakage for pumped storage plants when in partial pumping operations and the model administrative capabilities were modified to use OpenOffice instead of Microsoft Excel as the application which reads the model input files.

Additionally, a series of SR CHEOPS Model modifications were developed to support specific KT Relicensing Operating Scenario Committee (OSC) member group requests. The modifications included:

- The ability to specify reservoir fluctuation limits that are not a fixed elevation, but rather dependent upon the start-of-period elevation. This feature was added to support the request for fish spawning reservoir stabilization periods identified by the South Carolina Department of Natural Resources (SCDNR), and later was modified to be able to turn off this requirement when the LIP stage is other than "Normal."
- Enhanced support by upstream plants of downstream plant outflow requirements. The outflow enhancements take into account the sum of all required flows on the downstream plant, including required powerhouse outflows, wicket gate leakage, withdrawal requirements, and evaporation. This change prevents an upstream pumped storage or hybrid-pumped storage plant from pumping the downstream reservoir elevation too low when the downstream plant cannot meet its required flows releases.
- Pumped storage plant discharge operations may also be triggered/required without the requisite ability to pump back to support downstream plant outflow requirements.

A CHEOPS model is coded to run day-to-day operations based on a single set of operating conditions or rules. Actual hydroelectric operations generally follow the operating rules; however, human intervention periodically deviates from the general operating rules to accommodate day-to-day realities such as equipment failure and maintenance, changing hydrologic conditions, power demands, and other factors. In addition to differences between model operations versus actual operations that include human interventions, there are also inherent discrepancies due to input data inaccuracies (e.g., differences in calculated hydrology data, turbine or generator efficiencies, or reservoir storage curves). It is important to note CHEOPS model results cannot completely match historical or future operations due to these differences between actual operating conditions and modeled conditions.

Savannah River (SR) CHEOPS Model 4.2

The SR CHEOPS Model was originally developed during 2011-2013 to support relicensing of the KT Project based on input and physical characteristics included in the Savannah River ResSim model (HDR 2014b). It was custom-configured for the Upper Savannah River system based on the specific system constraints such as flow requirements, target reservoir elevations, powerhouse equipment constraints, and reservoir storage balancing between the Duke Energy

hydroelectric reservoirs (Bad Creek Reservoir, Lake Jocassee, and Lake Keowee) and downstream USACE hydroelectric reservoirs (Lake Hartwell, Richard B. Russell Lake, and J. Strom Thurmond Lake). Model output was evaluated by the OSC whose members represented relicensing stakeholder interests.

In support of the ongoing Bad Creek relicensing, the SR CHEOPS Model has been updated to reflect both mechanical and operational changes that have occurred since initial model development (i.e., since KT relicensing) and changes anticipated to occur during the term of the new Bad Creek license. These changes include:

- An updated reservoir storage curve for the Upper Reservoir.
- Upgraded units at the Project.³
- Requirements of the current KT Project FERC license.
- Updated pumping and generation dispatch tables for both Bad Creek and Jocassee
 Pumped Storage Station. These tables were revised to reflect anticipated changes in operation at both facilities as additional renewable generation is incorporated into Duke Energy's generation portfolio.

4.3 Model Verification

Model verification is intended to validate the input data and ability of the programmed logic in simulating daily hydroelectric and reservoir operations. HDR performed model verification of the SR CHEOPS Model during KT relicensing by using comparisons of actual and model-simulated generation and total discharge.

Verification of the model was completed using two different scenarios or model runs. The first performed a verification of the model input data, logic, and conditions for calendar years 1998 through 2008. This scenario is referred to as the historical baseline (A1). In addition to the historical baseline scenario, a second verification scenario (v2007) was developed to simulate the

³ On April 23, 2018, Duke Energy filed a Non-Capacity License Amendment Application to upgrade and refurbish the four Francis-type pump-turbines in the powerhouse, replace existing runners with Francis-type pump-turbine runners, and rehabilitate and/or upgrade the remaining components of the pump-turbine runners at the Bad Creek Project. Authorized Installed and Maximum Hydraulic capacities for the Project were increased to 1,400 megawatts (based upon the definition provided by 18 CFR §11.1[i]) and 19,760 cfs respectively.

detailed operations for calendar year 2007. Based on available historical generation records, modeled and historical generation were compared for the period 1998 through 2008 at all facilities except for Richard B. Russell. Generation at the Richard B. Russell development was only compared for the time period 2006 through 2008 because prior to 2006, Richard B. Russell pump units (four) were rarely operated. Generation data is commonly available for hydropower developments and is a metered value that has good accuracy compared to other forms of data that are not metered or based on estimated values with lower accuracy. The verification simulation was completed for hydrologic years with the best available historical reservoir operations over a wide range of hydrologic and reservoir operations conditions.

Generation is a measure of available flow and storage volume, which relates to inflows and reservoir elevations. When performing verification of water quantity models with power generation, it is common to find discrepancies between observed data and modeled output for generation and reservoir elevation when looking at a small sample of time periods (day, week, or month). This is due to the difference between the set of rules provided in the model vs. the day-to-day decisions common in large power developments that respond to power grid demands as well as storm forecasts and other non-measured impacts on the reservoir and equipment. Modeled results for each verification scenario were compared with historic generation, powerhouse flow, and reservoir levels. In addition to verifying the model under different hydrologic conditions, it was also important to select relatively recent years for model verification under conditions representative of current operating conditions.

As noted previously, the SR CHEOPS Model is coded to run day-to-day operations based on general operating conditions or rules. The model follows these rules strictly, 24 hours per day and 365 days per year, similar to an automated operation. Actual Project operations generally follow the operating rules, but deviations from general operating rules sometimes occur. Therefore, the verification goal is to obtain less than a five percent difference when comparing long-term modeled results to historical generation data over the hydrologic period. In cases where the modeled results exceeded a five percent difference, potential causes for the differences were examined to determine whether the difference was due to deviations in model setup, historical deviations in operations, or discrepancies in the reconstructed hydrology data.

4.3.1 Summary of Modeled Results versus Historical Operations

Verification of the SR CHEOPS Model was performed using historical operations data provided by Duke Energy and the USACE. The modeled flow releases from the hydroelectric facilities were compared to historical data to show whether the model provides a reasonable representation of hydroelectric operations throughout the year (e.g., timing, magnitude, and duration of operations).

The SR CHEOPS Model simulation of the historical baseline scenario (A1) estimated an average annual energy output two percent higher than historical generation for the same period, as shown in Table 4-1. There are significant annual swings in the percent difference between historical and modeled operations for the 1998 through 2008 period, with the largest variations at the Duke Energy facilities (as opposed to USACE facilities).

Table 4-1. Historical Base: Generation Comparison

Year Bad Creek		Jocassee Keowee		Hartwell	Richard B. Russell	J. Strom Thurmond	System Total	
1998	4%	12%	5%	2%		-4%	4%	
1999	7%	52%	-20%	0%		3%	14%	
2000	0%	47%	15%	11%		11%	10%	
2001	15%	16%	28%	11%		2%	14%	
2002	5%	-10%	-9%	12%		24%	3%	
2003	-9%	-9%	28%	24%		9%	-2%	
2004	12%	-5%	17%	2%		4%	6%	
2005	-3%	-10%	10%	3%		-8%	-4%	
2006	5%	1%	-13%	-6%	-4%	-13%	0%	
2007	-9%	6%	43%	21%	5%	12%	-1%	
2008	-14%	-46%	38%	10%	7%	15%	-16%	
Period Total (1998–2008)	0%	1%	10%	7%	2%	3%	2%	

Note: Prior to 2006, the Richard B. Russell pump units (four) were rarely operated, therefore comparisons consider 2006-2008 only.

Duke Energy facilities are operated on demand with a priority on peaking operations to optimize the value of generation based on energy pricing, whereas USACE facilities are operated on a weekly baseload schedule. The result is that the operations of Duke Energy facilities (especially pumping operations) vary greatly depending on the value of generation. For the period assessed (1998-2008), the Duke Energy system was only required to release water to stay in balance with

the system as outlined in the 1968 Operating Agreement⁴ regarding stored water sharing (releases) from the then planned KT Project. The USACE system was driven by a combination of the power requirements to SEPA, the system storage balance, and the minimum discharge requirements from the J. Strom Thurmond Development (HDR 2014a).

As shown in Table 4-1, there are significant swings between modeled and historical generation. There are many factors inherent in the model data and setup that can contribute to output discrepancies (i.e., deviations) when compared to historical data. In many cases, several of these factors may be involved simultaneously, which makes it difficult to isolate individual sources of difference. Four examples of potential sources of deviations from historical data are:

- **Pumping Operations** The model follows a set of defined rules for pumping, but it is seen in the historical records that pumping operations vary greatly from year-to-year, month-to-month, and even day-to-day. This is probably the single greatest contributor to deviations in the generation comparison and is also why the goal of this summary is to compare long-term trends rather than monthly or annual values.
- Hydrology The model uses reconstructed unimpaired flow data as the input for daily inflow to the system. The unimpaired hydrology was synthesized based on streamflow gage data and plant records, both of which have a certain amount of inherent error especially when multiple locations and data sources are involved. The overall hydrologic dataset appears to be a good representation of daily inflows and is acceptable for use in future water management planning.
- **Minimum Streamflow Requirements** The model is set up to account for minimum streamflow requirements automatically. As a result, the model is proactive in automatically addressing minimum streamflow requirements rather than reactive in providing excess flow to avoid potential violations, as may occur during actual operations.

⁴ The 1968 Operating Agreement was an agreement between Duke Energy, the US USACE Savannah District, and the Southeastern Power Administration (SEPA). It was superseded by the 2014 Operating Agreement between the same parties.

• Unit Outages and Performance – The model has been set up with post upgrade/rehabilitation unit performance information and does not take into account detailed unit outage information. For example, Units 1 through 4 at Hartwell were rehabilitated over the 11-year period of 1997 through 2007 but unit outages associated with the rehabilitation were not taken into account in the model.

In interpreting the information provided in the model operations/verification report (HDR 2014b), it is important to consider purpose of the model: to reasonably characterize operations at the generation facility under evaluation. Comparing model results with historical data confirms use of the model as a tool for simulating "real" operations. It is not possible within reasonable time and budget constraints to account for every outside influence or condition to match historical operations and hydrology.

Small changes in input data or model logic can often result in large changes in output. This is due to a number of reasons including (but not limited to) runoff characteristics, reliance on coordinated operations, and numerous/variable flow requirements. Each of these elements individually contributes to the sensitivity of the system. Combined, the sensitivity effects are multiplied. The input data and logic in the historical base scenario is an attempt to consolidate the effects of these variables to achieve an approximation of "characteristic operations."

The sensitivity described above also means that those factors that cannot be accounted for in the model (short-term operations decisions based on pricing, demand, forecasts, etc.) as well as data that are impossible to replicate exactly (synthesized hydrology data, shutdowns due to irregular maintenance, etc.) can result in relatively large discrepancies between modeled output and historical data on a per-month/per-development basis. The factors and sensitivity warrant careful model review with awareness of the potential for outliers. The ultimate acceptance of the results should not hinge on the extremes but rather on the overall impression of consistency between modeled and historical operations.

Most importantly, model verification should be used solely to assess the relative impacts between scenarios. In other words, model verification is really the only time it is appropriate to compare model results with historical data. As previously stated, verification is intended to validate the model input data and model logic so the "Base Case" becomes the baseline for all subsequent analyses.

Verification results show the model compares favorably to historical data, reasonably characterizes study area operations, and is appropriate for use in evaluating the effects of alternative operating scenarios. As with any model, accuracy is highly dependent on input data; consequently, model results should be viewed in a relative, rather than absolute, context. The CHEOPS model is a tool that can be successfully used to evaluate the relative sensitivity and response of the Project to changing operational constraints.

For more information about the validation of the SR CHEOPS model, see "Operations Model Study Savannah River Basin Model Logic and Verification Report" (HDR 2014b).

4.4 Project Data

4.4.1 Bad Creek Project

The Project uses the Bad Creek Reservoir as its upper reservoir and Lake Jocassee as its lower reservoir. The approximately 300-acre upper reservoir, formed by the damming of Bad Creek and West Bad Creek, has a drainage area of approximately 1.5 square miles (sq mi). Due to the small drainage area of Bad Creek Reservoir, inflows are minimal. The Bad Creek Reservoir normal maximum reservoir elevation is 2,310 feet (ft) above mean sea level (msl)⁵ with a minimum elevation of 2,150 ft msl.

The powerhouse contains four reversible motor-pump/turbine-generator units. There is no license-required operating guide curve; rather the reservoir is operated as needed for generation.

4.4.2 Jocassee Development

Lake Jocassee, which operates as the lower reservoir for the Project, was formed by impounding the Keowee River just downstream of the confluence of the Whitewater and Toxaway rivers. Lake Jocassee has a drainage area of 145 sq mi, a surface area of approximately 7,980 acres, and approximately 92 miles of shoreline at normal full pond (1,110 ft msl). Normal minimum pond elevation is 1,080 ft msl.

⁵ All vertical elevations in this report are National Geodetic Vertical Datum 1929 unless noted differently.

The Jocassee Development is a pumped storage facility with four reversible motor-pump/turbine-generator units. The SR CHEOPS Model uses an end of day target elevation of 1,107 ft msl.

The Jocassee Development and the downstream Keowee Development comprise the KT Project.

4.4.3 Keowee Development

Lake Keowee is formed by two parallel watersheds connected by a 2,000-ft-long canal. The watershed draining directly into Lake Keowee is approximately 439 sq mi. The reservoir surface area is approximately 17,660 acres at the normal full pond elevation of 800 ft msl.

Keowee Hydroelectric Station contains two conventional turbine-generator units. For SR CHEOPS modeling purposes, a target curve of 798 ft msl from May 1 to October 15, which then lowers gradually to 797 ft msl on January 1 and refills gradually by May 1, has been simulated to calculate usable storage for coordination with the USACE. Based on a review of historical operations of Lake Keowee, code was added to the SR CHEOPS Model for Lake Keowee to retain water in the Jocassee-Keowee pumped storage system for pumping and generating cycles. Because of this unique requirement, the model's target curve is not followed as strictly specified under normal hydroelectric reservoir operating conditions (HDR 2014b).

Based on the additional SR CHEOPS Model control at Lake Keowee, the model will not schedule discretionary releases from Lake Keowee unless the reservoir is nearing its normal full pond elevation and available storage for capturing runoff is reduced. This additional logic for Lake Keowee was applied and evaluated through verification of the model. This additional logic is user input whereas the SR CHEOPS Model can be adjusted to evaluate operational alternatives.

4.4.4 Hartwell Development

The Keowee Development releases water into the 55,900-acre Hartwell Lake which is operated by the USACE. Hartwell Hydroelectric Station has five conventional turbine-generator units. The Hartwell Development includes 5 ft of flood control storage from an elevation of 660 to 665 ft msl, which contains approximately 293,000 acre-ft of storage. A flood surcharge zone exists from 665 to 679 ft msl. A seasonally varying guide curve provides additional flood control during the winter and early spring. The minimum pool elevation is 625 ft msl (HDR 2014b).

4.4.5 Richard B. Russell Development

The 26,650-acre Richard B. Russell Lake is impounded by the USACE's Richard B. Russell Dam 30 miles downstream of the Hartwell Dam. The powerhouse contains four conventional turbine-generator units and four motor-pump/turbine-generator units. Two small house turbine-generator units were not modeled as part of the previous SR CHEOPS Model effort.

The Richard B. Russell reservoir includes 5 ft of flood control storage from an elevation of 475 to 480 ft msl. The limited conservation storage range between reservoir elevation 470 and 475 ft msl and fluctuation caused by pumping/generating cycles necessitates a constant guide curve with no seasonal drawdown (HDR 2014b).

4.4.6 J. Strom Thurmond Development

The 71,100-acre J. Strom Thurmond Lake is impounded by the J. Strom Thurmond Dam. The dam is located 37 miles downstream of the Richard B. Russell Dam. The powerhouse contains seven conventional turbine-generator units.

The objective of flood control regulation at the J. Strom Thurmond project is to reduce flood damages to the lower Savannah River basin to the extent possible. Normal pool varies seasonally from 330 ft msl April 1 through October 15; and between October 15 and December 15, the pool is drawn down to a seasonal normal pool of 326 ft msl to allow for the statistically higher winter and spring inflows. Starting January 1, the pool is refilled to reach 330 ft msl on April 1 (HDR 2014b).

4.5 Hydrology

The hydrologic dataset, Savannah River Unimpaired Flow 1939-2008 Time Series Extension Report (ARCADIS 2010), applied in the SR CHEOPS Model was provided by ARCADIS and prepared for Duke Energy, the Savannah District of the USACE, and the Georgia Environmental Protection Division (EPD). The study performed by ARCADIS developed unimpaired incremental flow (UIF) time series data (UIF database dated September 16, 2010) for the five hydroelectric developments on the Savannah River from Lake Jocassee to J. Strom Thurmond Lake. Due to the small size of the Bad Creek watershed, HDR developed the UIF to Bad Creek as a portioned one percent of the developed Jocassee UIF. As outlined in the Savannah River

Unimpaired Flow 1939-2008 Time Series Extension Report released by ARCADIS on August 12, 2010, these data are suitable for the following purposes:

- Reservoir system operational modeling by Duke Energy and the USACE, with the USACE serving as a cooperating agency for the FERC relicensing of Duke Energy's **KT** Project
- Reservoir operational planning studies by the USACE
- Determination of desired flow regimes and consumptive water-use assessments for Georgia EPD

The excerpt below from Section 1 of the Savannah River Unimpaired Flow 1939-2008 Time Series Extension Report (ARCADIS 2010) defines the methods applied in the development of the UIF time series data. All time series data were supplied in the USACE'S Hydrologic Engineering Center Data Storage System (HEC-DSS) databases.

Incremental and cumulative UIFs are developed for the Seneca River at the Jocassee and Keowee sites from historical stream flows and reservoir releases at these locations by removing (1) effects of reservoir regulation (holdouts and releases from storage), (2) differential pre- and post-reservoir net evaporation (i.e., evaporation minus precipitation excess from the reservoir surface area), and (3) consumptive water uses within the respective local drainage areas. General assumptions and methods applicable to UIF development under this study are subsequently described as follows.

- The period of record (POR) for UIFs developed under this study uniformly extends from January 1939 through December 31, 2008. UIFs previously developed by Georgia EPD for 1939–2007 (Georgia EPD 2010) were recalculated.
- Daily incremental UIFs were developed at the following nodes within the Savannah River basin: Jocassee (Seneca River); Keowee (Seneca River); Hartwell, Richard B. Russell (U.S. Geological Survey [USGS] gage 02189000, Calhoun Falls); Bell (Broad River, USGS gage 02192000); Thurmond, Augusta (USGS gage 0219700); Burtons Ferry (USGS gage 02197500); Millhaven (Brier Creek, USGS gage 02198000); and Clyo (USGS gage 02198500).

- Georgia EPD has provided daily potential evapotranspiration (PET) time series data computed using the Hamon equation that extend from January 1, 1939 to December 31, 2008. These have been used in the computation of reservoir evaporation following procedures used in the development of the January 1, 1939 to December 31, 2007 UIF time series.
- Federal and non-federal reservoir holdouts, net evaporation, and daily inflows and outflows have been computed and applied as appropriate to UIF derivation. For reservoirs where time series data required for these calculations are not available, run-of-river operation has been assumed. Operational data were provided by Duke Energy, including Bad Creek Reservoir elevation time series data and elevation and outflow time series data for the Jocassee and Keowee projects, in addition to elevation-area-storage paired data for the Keowee and Jocassee projects.
- UIF data development has been primarily accomplished by filling and routing of missing 1939 to 2008 historical flow data and by adjustments for reservoir effects and water uses. Techniques may involve application of Riverside's TSTool software and USACE DSS utilities, interactively and by batch programming. All time series and paired data have been stored in HECDSS databases and map-referenced as approved by Georgia EPD. UIF development has largely relied upon time series previously developed by ARCADIS U.S., Inc. (ARCADIS) for Georgia EPD.
- Historical water use data, on a daily or monthly time step, have been provided by Georgia EPD in electronic form quality-controlled and suitable for UIF development. Water use data extends from 2005 to 2008.
- Routing techniques for observed flow filling and UIF derivation have been selected by ARCADIS for consistency with existing 1939 to 2007 Savannah UIF data previously developed for Georgia EPD.

Additional information on the development of the UIF is available in the Savannah River Unimpaired Flow 1939-2011 Time Series Extension Report revised by ARCADIS in May 2013 (ARCADIS 2010, 2013).

During the initial stages of the model scenario development phase of the KT Project relicensing process, the OSC identified the desire to have a Savannah River Basin inflow dataset that

verified well against the most severe historical drought period on record, the 2007-2008 drought. Through a review of inputs and assumptions used in the SR CHEOPS Model, the OSC concluded there was too much water accounted for in the back calculated incremental inflow time series. The OSC requested an investigation to determine the source of the apparent inconsistency in the inflow time series during 2007-2008 when comparing modeled results to historical data. ARCADIS assisted HDR with a review of the inflow time series development and documentation. The review compared the inflow time series to USACE calculated inflow series and recommended using a different combination of inflow data (from within the September 2010 HEC-DSS database) for all reservoirs with the most significant differences in the Richard B. Russell Lake. These datasets were pulled from the supplied September 2010 HEC-DSS files. The OSC approved revising the model inflow data series in the SR CHEOPS model.

The 1939 through 2008 hydrologic dataset adopted by the OSC in August 2012 was used for KT model relicensing scenario development from September 2010 through December 2012. In the fall of 2012, Duke Energy, following a recommendation from the OSC, funded an extension of the inflow dataset by three years. The inflow dataset was extended by ARCADIS using the same methodology developed to construct the original dataset expanding the period of record (POR) to 1939 through 2011. The final revised dataset was provided by ARCADIS on May 13, 2013, and extended the existing inflow hydrology files in the SR CHEOPS model as described in detail in the May 2013 Savannah River Unimpaired Flow Data Report (ARCADIS 2010, 2013).

4.6 Baseline Scenario

4.6.1 Logic

Figure 4-1 and Figure 4-2 provide an overview of the model logic in sequence.

Figure 4-1. CHEOPS Model Execution Flow Chart

Figure 4-2. CHEOPS Scheduling Flow Chart

4.6.2 Input Data

The input data listed in the following subsections show the general operational constraints and physical parameters used in the SR CHEOPS Model to define the existing system configuration for the Baseline scenario setup. The following subsections are organized by the four components that define a CHEOPS scenario, as shown on Figure 4-3.

Figure 4-3. CHEOPS Scenario

4.6.3 System Data

4.6.3.1 Load Shapes and Energy Values

This section contains the load shape and energy value data common to the facilities on the Savannah River. The SR CHEOPS Model load shape defines the daily schedule, on an hourly basis, of relative power pricing and the hour durations of each price in the peak, off-peak, and shoulder periods, as presented in Table 4-2 and Table 4-3. The model uses the load shape data to schedule the release of water throughout the day, prioritizing generation during peak periods. Durations for the load shape reflect anticipated changes in operation as additional renewable generation is incorporated into Duke Energy's generation portfolio.

Table 4-2. Load Shape – Weekday Schedule

Weekday Schedule (hours/day)							
Month	Morning Off Peak Peak Morning Peak Afternoon Secondary Peak Peak Peak Peak Evening Secondary Peak Peak						
January	1	5	2	10	3	3	
February	1	5	2	10	4	2	
March	1	5	2	11	2	3	

	Weekday Schedule (hours/day)

November	6	2	9	5	2		
December	6	2	9	6	1		

4.6.3.2 Carry-Over Elevations Condition

The Carry-Over Elevations Condition controls how to treat the beginning-of-year and end-of-year elevations. The model begins a run (scenario simulation) on January 1 of the start year with each reservoir at its target elevation. If the scenario is run for a multiple year period, then the model can either start subsequent years with the reservoirs at the target elevations or at the end of previous year elevations.

The Carry-Over Elevations is selected (i.e., the checkbox is checked) in this model. Therefore, the model will carry-over the end-of-year elevations to the next year, and reservoirs will start the next year at the ending elevations of the previous year.

4.6.3.3 Forecast Set-Up Condition

The Forecast Set-Up Condition requires two inputs: a number of forecast days, and an accuracy of the forecast. The number of days is how many days the model looks ahead in the inflow file to calculate how much water the system is going to receive. The model is set up to look 1 day ahead with 100 percent accuracy. Since the model has "perfect" forecasting as it looks at the actual inflow file, the accuracy setting allows the user to adjust the model's ability to forecast accurately. The accuracy setting adjusts inflow by a fixed multiple. The model looks ahead the given number of days, adds up the inflows, multiplies those inflows by the entered accuracy value, then schedules releases based on this forecasted inflow volume. If the accuracy setting is not 100 percent (1.0), then the forecasted volume is not accurate. By running the model with 90 percent (0.9) accuracy, and then running again at 110 percent (1.1) accuracy, the user can simulate operations where the operator has an ability to forecast inflows plus or minus 10 percent.

4.6.3.4 Operating Agreement (Storage Balance Operations)

This section provides details of the storage relationship between the Duke Energy and USACE facilities resulting from the development of the 2014 Operating Agreement which is implemented as part of the Baseline scenario for use during ongoing Bad Creek relicensing.

On October 1, 1968, Duke Energy's predecessor company, Duke Power Company, entered into 1968 Operating Agreement with the USACE Savannah District and SEPA regarding stored water sharing (releases) from the planned KT Project. The 1968 Operating Agreement was replaced by the 2014 Operating Agreement in conjunction with KT Relicensing.

The 2014 Operating Agreement defines balancing of the available storage in Duke Energy reservoirs (Bad Creek, Jocassee, and Keowee) with USACE available storage (Hartwell, Richard B. Russell, and J. Strom Thurmond) according to storage balance rules as outlined in the 2014 Operating Agreement. The SR CHEOPS Model incorporates the terms of the 2014 Operating Agreement through a series of programming rules where balance checks are performed on

weekly basis. These rules are integral in simulating the storage relationships between the developments and significant time was spent refining these rules in the SR CHEOPS Model.

When a tandem or parallel reservoir system is defined within the SR CHEOPS Model, the model determines the priority and the amount of release to make from each reservoir to operate towards a user-defined storage balance. For every decision interval, an end-of-period storage is first estimated for each reservoir based on the sum of beginning-of-period storage and period average inflow volume, minus all potential outflow volumes. The estimated end-of-period storage for each reservoir is compared to a desired storage that is determined by using a system storage balance scheme. The priority for release is then given to the reservoir that is furthest above the desired storage. When a final release decision is made, the end-of-period storages are recomputed. Depending on other constraints or higher priority rules, system operation strives for a storage balance such that the reservoirs have either reached their guide curves or they are operating at the desired storage (percent of the active storage zone).

The storage balance operations of the system are simulated in CHEOPS using an OpenOffice-based input sheet referenced by the CHEOPS drought plan input. Each reservoir in the system from Lake Jocassee to J. Strom Thurmond Lake is simulated with a drought plan. The USACE developed and updated the DCP to help sustain the basin's water supply needs for domestic and industrial water users, navigation, and environmental protection. To decelerate the decline in reservoir elevations during the early stages of drought, the USACE reduces weekly average flow releases from the Hartwell and J. Strom Thurmond developments. Once the DCP has been activated, flows are reduced in a step-wise fashion starting with a reduction of downstream releases from J. Strom Thurmond Lake. Reservoir elevations at Lake Hartwell and J. Strom Thurmond Lake are kept in balance during both normal and drought conditions.

During 1988 drought conditions, the J. Strom Thurmond and Hartwell Lakes were almost 17 and 15 ft below the top of their conservation pools, respectively. (The conservation pool is the amount of usable storage in the reservoir.) Accordingly, during the 1988 drought period, the USACE was not able to fully meet authorized project purposes. This led the USACE to initially develop the 1989 DCP with three trigger levels (USACE 1989). In 2006, the DCP was revised to include a fourth trigger level. The 2006 DCP allows the USACE to maintain higher pools at the reservoirs without further impacts to any water intakes upstream or downstream of the dams. In

2012, the DCP flows required out of J. Strom Thurmond Lake were revised, along with the addition of an inflow trigger.

The reservoir storage at the Bad Creek Project and Richard B. Russell developments are not included in the DCP. However, for model stability purposes and implementation of the KT LIP, Bad Creek reservoir and Richard B. Russell Lake storage are included in the CHEOPS Model storage index calculations while using a rule-link but no reservoir storage adjustments are required. Each reservoir in the system is linked to its downstream reservoir (except as noted) with a system storage balance relationship. The storage balance definition defines the rate of drawdown at each reservoir in relation to the next downstream reservoir and is user definable. The application of the storage balance definition simulates the system in accordance with the 2014 Operating Agreement and the USACE DCP.

4.6.3.5 Low Inflow Protocol (LIP)

This section provides details of the SR CHEOPS Model functionality to simulate the LIP.

The LIP specifies how Duke Energy will operate the Bad Creek and KT Projects during droughts. The LIP includes five stages based on specific triggers (i.e., remaining usable storage and DP levels, stream flows, and the U.S. Drought Monitor⁶). The LIP also specifies maximum reservoir drawdowns and maximum downstream flow releases from Keowee Hydro Station based upon the specific LIP stage. It should also be noted the remaining usable storage for determination of LIP stage (only applicable at Duke Energy reservoirs) is based on normal full pond elevations.

The SR CHEOPS Model incorporates the terms of the LIP as outlined in the KT Project FERC license through a series of programming rules. The LIP functionality was added to the SR CHEOPS during KT Relicensing to enable LIP stage definitions and specify required actions for each LIP stage. Model logic measures, on the specified day, the Duke Energy usable storage based on full pond elevations and gage hydrology, then implements the LIP stage change after the appropriate delay. The LIP adds Bad Creek and Richard B. Russell reservoirs to the USACE

⁶ The U.S. Drought Monitor is produced by the National Drought Mitigation Center at the University of Nebraska-Lincoln, the National Oceanic and Atmospheric Administration, and the U.S. Department of Agriculture. It blends precipitation, streamflows, temperatures, evaporative demand, and other factors to interpret drought conditions.

DCP usable storage calculations, which required modifications to the USACE DCP input file. The modifications to the USACE DCP file to reflect the LIP include specifying whether to include the Bad Creek and Richard B. Russell reservoirs in the usable storage calculation, and also provided cells for inputting the elevation which is considered bottom of usable storage pool for all six reservoirs.

Additional SR CHEOPS model parameters associated with the LIP include:

- The minimum elevation for Lake Keowee is 790.0 ft msl. However, the elevation will remain above 791.5 ft msl until the Duke Energy system remaining usable storage is at or below 12 percent (see Table 4-4).
- The percentage of Duke Energy remaining usable storage at which the outflow from Lake Keowee is limited to evaporation, water use, and leakage is 12 percent.
- The LIP minimum reservoir elevations for each LIP stage as listed in Table 4-4.
- The Lake Keowee water release calculation uses 790.0 ft msl as the minimum Lake Keowee reservoir elevation for the calculation of Duke Energy remaining usable storage.
- The Jocassee minimum reservoir elevation for the calculation of Duke Energy remaining usable storage is 1,080.0 ft msl.
- Full pond at the Duke Energy reservoirs is defined as the maximum elevation in the remaining usable storage calculation.
- The volume of storage in the Bad Creek Upper Reservoir from elevation 2,310.0 ft msl to 2,150.0 ft msl is included in the calculation of Duke Energy storage balancing contribution with the USACE system.
- The volume of storage in the Richard B. Russell reservoir between elevations 475.0 ft msl and 470.0 ft msl is included in the USACE remaining usable storage balancing calculations.

The Baseline scenario references USGS gage averaging using a 4-month rolling average and LIP logic to reference "triggered" DCP level versus "in-effect" DCP level during LIP recovery. The referenced DCP level allows the LIP to change more quickly to a lower stage number during the recovery process, eliminating the 2-ft recovery delay in the USACE's DCP.

Table 4-4. Lakes Jocassee and Keowee Low Inflow Protocol Stage Minimum Elevation

I ID Stogo	Lake Jocassee Elevation	Lake Keowee Elevation
LIP Stage	(ft msl)	(ft msl)
0	1,096.0	796.0
1	1,092.0	795.0
2	1,087.0	793.0
3	1,083.0	792.0
4	1,080.0	791.5*

^{*}Note: In LIP Stage 4, the Keowee reservoir elevation will be maintained at or above 791.5 ft msl until the Duke Energy storage balance reaches 12 percent. The minimum elevation used to calculate the usable storage for storage balancing with the USACE is 790.0 ft msl.

Additionally, LIP/DCP functionality includes the following logic:

- Functionality to allow the user to limit spring lake stabilization to LIP Stage 0 (Normal).
- Functionality to allow the user to specify that the USACE and Duke Energy reservoir storage balancing logic use full pond elevation versus target elevation at Duke Energy reservoirs for calculations of usable storage.
- Functionality to fine-tune simulated Lake Keowee operations and limit discharge from Lake Keowee by allowing the user to define a percentage above the target curve (published in the 1968 Operating Agreement) for the model to attempt to maintain a Full Pool.
- Functionality to allow the user to define two Maximum Required Weekly Release volumes from Lake Keowee for LIP Stage 4. The first is based on a Duke Energy Percent Usable Storage Remaining trigger and the second is the default if less than the defined Duke Energy Percent Usable Storage Remaining.
- Functionality to allow the user to revise the LIP logic to reference "triggered" DCP level versus "In-Effect" DCP level during LIP recovery. This allows the LIP to more quickly change to a lower stage number during recovery process, eliminating the 2-foot recovery delay in DCP protocol.
- Ability to set lake level fluctuation base elevation to be set at the lowest instantaneous elevation from the day prior to the start of the lake stabilization period.

4.6.3.6 System Power

The USACE developments have a power generation requirement with SEPA to achieve a minimum generation value (HDR 2014b). The weekly generation requirement can be met by any

s FOR

combination of the three USACE plants, and the requirement value varies by month. The weekly targets are based on power contracts with SEPA, as listed in Table 4-5. These values are currently entered into the model in the Drought Plan input sheet.

Table 4-5. Weekly Target Generation from USACE Projects

Month	Weekly Target Generation (megawatt-hours)
January	27,233
February	26,714
March	20,669
April	18,504
May	21,948
June	25,935
July	31,195
August	32,035
September	30,685
October	27,304
November	26,284
December	27,104

4.6.4 Physical Data

4.6.4.1 Reservoir Storage Curves

The Reservoir Storage Curve is a tabulated link between the reservoir elevation and reservoir volume. The model uses this curve to calculate elevations based on inflows and model-determined releases. Figure 4-4 shows the Bad Creek reservoir storage curve based on LiDAR data collected in 2018.⁷ The Lake Jocassee and Lake Keowee storage-volume relationships were based on bathymetric data collected in 2010 (Figure 4-5 and Figure 4-6) and the USACE storage-volume relationships for Hartwell, Richard B. Russell, and J. Strom Thurmond lakes (Figure 4-7 through Figure 4-9) were based on published storage-volume relationships revised based on applying regional sedimentation rates from the Savannah River basin. Sedimentation rates were converted to sediment volume using methods outlined in USACE Engineer Manual 1110-2-4000 and estimated compressed density of the sediment⁸.

⁷ Values for 2110 feet and lower are based on historic 1974 data.

⁸ Storage volume curves for the USACE reservoirs are identical to those used during KT relicensing. No additional sedimentation was calculated.

Figure 4-6. Keowee Reservoir Storage Volume Curve

Figure 4-7. Hartwell Reservoir Storage Volume Curve

Figure 4-8. Richard B. Russell Storage Volume Curve

Figure 4-9. J. Strom Thurmond Reservoir Storage Volume Curve

4.6.4.2 Reservoir Area Curves

The Reservoir Area Curve is a tabulated link between the reservoir elevation and reservoir surface area. The model uses this curve to calculate the surface area and uses this data for computing evaporation losses. Figure 4-10 through Figure 4-15 show the reservoir area curves used in the model.

Figure 4-10. Bad Creek Reservoir Area Curve

Figure 4-13. Hartwell Reservoir Area Curve

Figure 4-14. Richard B. Russell Reservoir Area Curve

Figure 4-15. J. Strom Thurmond Reservoir Area Curve

4.6.4.3 Monthly Evaporation

Evaporation is based upon a monthly varying coefficient that defines the evaporative loss per reservoir. This evaporative loss is not strictly composed of losses due to evaporation, but rather a net change to inflows due to evaporation, direct precipitation to water surface, precipitation runoff, and changes to evapotranspiration losses. Negative values indicate a net inflow to the reservoir. Based on the median data, the precipitation inflow to the reservoir exceeds the evaporation from the reservoir. This coefficient (which is entered into the model in ft per day per acre) is multiplied by the surface area of the reservoir to compute total evaporative loss volume for the reservoir. Table 4-6 shows the SR CHEOPS Model evaporation loss coefficients for each reservoir by month. The evaporation loss coefficients reflect the monthly 2008 values published by ARCADIS in the Savannah River Basin May 13, 2013, time series release (ARCADIS 2010, 2013). The September 16, 2010 ARCADIS time series release contains the same 2008 evaporation values as provided in the May 2013 release.

Table 4-6. Evaporative Loss Coefficients

4.6.4.4 Tailwater Data

The Tailwater Curve relates the powerhouse tailwater elevation to the development's outflow. In cases where the powerhouse releases directly into a downstream reservoir, the downstream reservoir's elevation is used to compute tailwater elevation. The tailwater elevation is subtracted from the reservoir elevation to calculate the gross head used in determining turbine and pumpturbine hydraulic performance.

Bad Creek releases directly into Lake Jocassee, so the elevation of Jocassee is the controlling factor for Bad Creek's tailwater elevation. Likewise, the Jocassee powerhouse releases directly into Lake Keowee, so the elevation of Keowee is the controlling factor for Jocassee's tailwater elevation computation.

The Keowee powerhouse discharges into Hartwell Lake. However, due to backwater effects in the upstream lake channel, there is a difference between Hartwell Lake elevation (at Hartwell Dam) and the water surface elevation below the Keowee powerhouse when the turbines are in operation. Table 4-7 shows the Keowee Development's powerhouse tailwater curve in stage units of ft msl for various powerhouse outflows in cfs.

Table 4-7. Keowee Powerhouse Tailwater Rating Curve

Stage (ft msl)	Flow (cfs)	Stage (ft msl)	Flow (cfs)
657	0	680	39,867
660	5,042	684.8	59,879
665.1	11,345	689.9	85,879
670	16,545	695	113,612
674.9	26,000		

Similar to Bad Creek and Jocassee Hydro, the Hartwell powerhouse releases directly into Richard B. Russell Lake without backwater effects. Therefore, the Richard B. Russell Lake elevation is the control for Hartwell Hydro Station's tailwater elevation. The CHEOPS Model uses the greater of 475 ft msl or Richard B. Russell Lake water surface elevation. Reservoir elevation 475 ft msl is the minimum tailwater elevation provided by the USACE for modeling purposes.

Richard B. Russell powerhouse releases into J. Strom Thurmond Lake. The J. Strom Thurmond Lake elevation is the control for Richard B. Russell's tailwater elevation. The J. Strom Thurmond tailwater rating curve is shown in Table 4-8.

Table 4-8. J. Strom Thurmond Powerhouse Tailwater Rating Curve

Stage (ft msl)	Flow (cfs)	Stage (ft msl)	Flow (cfs)
187	0	220	280,000
190	15,000	230	440,000
200	65,000	240	640,000
210	155,000	250	870,000

4.6.4.5 Spillway Capacity

The Spillway Curve contains the data relating reservoir elevation and spillway discharge capacity. These data allow the model to determine the maximum amount of water that can be spilled at the current reservoir elevation and is the sum of all spillway conveyances with gates open to maximum setting. The CHEOPS Model allows for a simple spillway relationship of elevation and flow; therefore, all spillways, including gates, are modeled as a relationship of elevation and flow.

Spillway capacity data for the Bad Creek Project is shown in Table 4-9, derived from the Bad Creek Pumped Storage Project Supporting Technical Information Document (Duke Energy 2008). The Bad Creek emergency spillway is also known as the East Dike.

Table 4-9. Bad Creek Spillway Values

Elevation (ft msl)	Capacity (cfs)	Elevation (ft msl)	Capacity (cfs)
2,313.5	0	2,315	2,313
2,313.8	17	2,315.5	4,477
2,314.3	477	2,316	7,153
2,314.6	1,051		

Table 4-10 shows the maximum spillway capacity of the two-gated spillways as delineated in the Jocassee Development Supporting Technical Information Document (HDR 2010).

Table 4-10. Jocassee Total Gated Spillway Capacity Values

Elevation (ft msl)	Capacity (cfs)	Elevation (ft msl)	Capacity (cfs)

4.6.4.6 Plant Operation Type

The Plant Operation Type is how the CHEOPS model classifies and operates the plants. Four different components are used to describe the operation of the plants.

• **Min Powerhouse Flow** – All plants in this model have zero (0) value entered, as the turbine input curves accurately define the lowest operating flow of the units.

- Plant Operation Type This condition specifies what type of scheduling logic is to be used for the plant. Options include Strictly Peaking, Non-generating, Run-of-River, and others. The plant operation types for the nodes in this model are shown below. Pumped storage plants follow pumping and discharge schedules. Strictly Peaking plants use logic to generate as much power as possible during the peak period, followed by secondary-peak and then off-peak periods. Hybrid-pumped storage plants have a pumping schedule, but schedule plant discharge using peaking plant logic.
 - o Bad Creek Pumped Storage
 - o Jocassee Hybrid-Pumped Storage
 - o Keowee Strictly Peaking
 - o Hartwell Strictly Peaking
 - o Richard B. Russell Hybrid-Pumped Storage
 - o J. Strom Thurmond Strictly Peaking
- **Delinked Owner** This condition sets the level of water conveyance support a plant receives and provides to other plants operated by the same licensee/operator. All plants in the model have this value unchecked, meaning the plants provide supporting operation to other plants operated by the same owner.
- Delinked System This condition sets the level of support a plant receives and provides to other plants operated by other licensees/operators in the modeled system.
 All plants in this model have this condition checked, meaning the default CHEOPS logic for support between plants is not in effect for plants operated by different operators. In this model, other methods and rules of setting the support between plants and owners are used.

4.6.5 Operational Data

4.6.5.1 Spill and Minimum Elevations

The spill or flood control elevation relates to a variety of physical situations (spillway crest, partial gate coverage, maximum normal pool, etc.), but it represents the elevation at which the model will begin to simulate spill to avoid increasing water elevation. Under a Strictly Peaking plant, when the model calculates an end-of-period elevation above the spill elevation, the model will calculate spill as well as the turbine/diversion discharge. The model's logic, under a Strictly

Peaking plant, also attempts to reduce or eliminate occurrences when the reservoir elevation exceeds the spill elevation.

The minimum elevation is the minimum allowable reservoir elevation. This elevation could be set by regulations or by a physical limit (lowest available outlet invert). Bypass flows, withdrawals, wicket gate leakage, and evaporation can draw the reservoir below this level. The model will operate to eliminate occurrences when the reservoir elevation dips below this elevation.

Table 4-15 lists the spill and minimum elevations for each development in the model.

Spill Elevation Minimum Elevation Development (ft msl) (ft msl) **Bad Creek** 2,310 2,150 1,110 1,080 Jocassee 790 Keowee 800 Hartwell 665 625 Richard B. Russell* 475.3 470 J. Strom Thurmond 335 312

Table 4-15. Reservoir Spill and Minimum Elevations

4.6.5.2 Target Elevations

The Target Elevation is the user-defined elevation that the model attempts to meet (targets) as the end-of-day reservoir elevation. The model straight-line interpolates between user input points to identify a target elevation for each day. The model will deviate from the target to accommodate forecasted inflows, to meet the plant's own outflow requirements or constraints, and to support downstream minimum flow requirements from the J. Strom Thurmond development.

Table 4-16 lists the guide curve elevations for the Duke Energy reservoirs (curves needed for modeling), and Table 4-17 lists the guide curves for the USACE reservoirs. Target requirements for the USACE developments were provided by the USACE with the Savannah River ResSim Model (HDR 2014b).

^{*} Richard B. Russell spill elevation set to 475.3 ft msl and spillway capacity set to zero below 480 ft msl to support logic to prevent pumping above 475 ft msl.

4.6.5.3 Water Withdrawals

Historical water use (withdrawals and returns in cfs) were estimated as part of the Savannah River Basin September 16, 2010, UIF time series release (ARCADIS 2010, 2013). The median 2003-2008 monthly water use in cfs was modeled in the historical baseline scenario to represent historical municipal and industrial water use from each reservoir. Table 4-18 shows the historical baseline scenario modeled withdrawals and returns in cfs. The example calculation below describes the withdrawal calculation for a reservoir for a month:

$$WR_{RI,Month} = Median(WR_{Day,Year})$$

where:

 $WR_{R1,Month}$ is the net withdrawal (in cfs) for the reservoir for the month $WR_{Day,Year}$ is the withdrawal (in cfs) for the reservoir for each day of the month for each of the months of interest in the 2003 through 2008 period.

During KT relicensing, Duke Energy contracted with HDR to complete a Water Supply Study of the Savannah River Basin. This study is detailed in the *Final Keowee-Toxaway Water Supply Study Report* (HDR 2014c). The Water Supply Study provided the following data which have been adopted for the Project scenarios, including the scenarios outlined in this report:

- Water withdrawals and returns within the Savannah River Basin (Basin) that are greater than or equal to 100,000 gallons per day (HDR 2014b).
- Future projections for water withdrawals and returns within the Basin to the year 2066.

The withdrawals and returns simulated in the Water Supply Study are included in Appendix A of this report.

4.6.5.4 Minimum Flows

The Hartwell, Richard B. Russell, and J. Strom Thurmond developments have fish spawning rules in the SR CHEOPS Model. The rule requires outflow to equal inflow if the reservoir is at or below target elevation during the month of April. Additionally, J. Strom Thurmond Lake has a required average daily discharge of at least 3,800 cfs year-round.

4.6.5.5 Maximum Flows

The model allows a Maximum Flow constraint to be applied either at a powerhouse or at a downstream node. This will limit operations to restrict flow to a maximum of the defined limit. The J. Strom Thurmond development has a maximum flow restriction at the downstream node in Augusta, Georgia, depending on the reservoir elevation of J. Strom Thurmond Lake. If the lake elevation is below 330 ft msl, the maximum allowable flow at Augusta is 20,000 cfs; if the reservoir elevation is greater than or equal to 330 ft msl, the maximum allowable flow is 30,000 cfs. These flow restrictions are based on goals for normal operation at the development. Under extreme flooding, these flows can be exceeded.

The Richard B. Russell development has a maximum flow constraint of 60,000 cfs, and the Hartwell development has a maximum flow constraint of 28,500 cfs.

4.6.5.6 Pump Operations

Bad Creek uses pumped storage logic and Jocassee and Richard B. Russell use hybrid-pumped storage logic. These settings require pump operations schedules. Bad Creek pump operations specify pumping and discharge schedules (specified in the tables by number of units available to operate), while Jocassee and Richard B. Russell specify pumping only. In Table 4-19 through Table 4-21, pump operations schedules are described by negative numbers. The magnitude of each negative number indicates the number of units available for pumping during a given hour. Table 4-19 includes positive numbers, which indicate discharge during a given hour. Durations for the Bad Creek and Jocassee schedules reflect anticipated changes in operation as additional renewable generation is incorporated into Duke Energy's generation portfolio.

The model will deviate from the user-specified pumping or generating schedule when certain conditions are encountered, such as when the upper reservoir is approaching the spill elevation, the lower reservoir is approaching the minimum elevation, and when a powerhouse is undergoing maintenance. Additionally, the model will attempt to avoid operations that may empty the upper reservoir, cause spill at the downstream reservoir, or end the day significantly different from the target elevation. The model does this by evaluating the starting elevation, desired ending elevation, and user-specified pumping and generating unit-hours for the day. Using pumping and generating volume capacities at the start of the day, the model will adjust

(reduce only), the number of unit-hours to balance the generation volume and pumping volume, taking into account the desired daily change in storage. For example, if a user inputs four unit hours of generation and four unit hours of pumping, the model will reduce the generation unit-hours to three so the total volume released from the upper reservoir can be made up with the four unit hours in the pump schedule.

For hybrid-pumped storage logic, the model will pump with the specified number of units during the hours specified unless the upper reservoir approaches spill elevation, the lower reservoir approaches minimum elevation, or units are in maintenance. The generation release scheduling of a hybrid-pumped storage plant occurs just as if the plant is a typical peaking plant, where outflow is determined by change in storage and inflow, which includes upstream plant discharge, upstream plant bypass flow return, upstream plant spill, incremental accretion, water withdrawal returns, and pumping operations. A powerhouse will not be scheduled to release for generation if an hour has been specified for pumping operations and pumping was actually scheduled.

4.6.6 Generation Data

Unit performance information was modeled based on the information available at the time of model development.

4.6.6.1 Headloss Coefficients

The CHEOPS model allows two common headloss coefficients for each plant and an individual coefficient for each unit. Headloss for each unit is calculated by multiplying the unit's common

coefficient by the total flow for that common coefficient squared added to the individual coefficient multiplied by the individual unit flow squared. The formula is:

$$H_i = \left(\sum_{j=1}^n F_i\right)^2 h_C + F_i^2 h_i$$

Where:

H_i is the unit headloss in ft

h_c is the common coefficient for the ith unit

h_i is the individual coefficient for the ith unit

F_i is the flow for the ith unit

j runs from 1 to n

n is the number of units that have the same common coefficient as the unit i

Table 4-22 presents the estimated headlosses for each plant as a function of flow (Q):

Common Common **Development** Unit 1 Unit 2 Unit 3 Unit 4 Unit 5 Unit 6 Unit 7 Unit 8 2 1.25E-07 **Bad Creek** Jocassee 1.41E-08 1.41E-08 6.99E-08^a 6.99E-08^a 6.99E-08^b 6.99E-08^b Keowee 1.22E-08 2.33E-08^a 2.33E-08^a Hartwell 3.55E-08 3.55E-08 3.55E-08 3.55E-08 Richard B. 2.40E-08 2.40E-08 2.40E-08 2.40E-08 2.40E-08 2.40E-08 2.40E-08 2.40E-08 Russell J. 4.6.6.2 Turbine Efficiency Curves

Turbine performance is entered by plant and as flow versus efficiency at five separate net heads. The Bad Creek Powerhouse contains four reversible motor-pump/turbine-generator units with a design head of 1,115 ft msl. The modeled performance of the turbines in generation mode is presented in Table 4-23. The Jocassee powerhouse also contains four reversible motor-pump/turbine-generator units; modeled performance is presented in Table 4-24.

The Keowee powerhouse contains two similarly sized conventional turbine-generator units. The modeled performance of these turbines is presented in Table 4-25. The Hartwell powerhouse contains five conventional turbine-generator units, four of which were rehabilitated over the 11-year span of 1997 through 2007. The Richard B. Russell powerhouse contains four similarly sized conventional turbine-generator units and four reversible turbine-generator/motor-pump units. The J. Strom Thurmond powerhouse contains seven similarly sized conventional turbine-generator units. The modeled performance of the USACE turbines is presented in Table 4-26 through Table 4-29.

4.6.6.3 Generator Efficiency Curve

The generator data, like the turbine data, is entered by plant and then associated with a unit. The generator performance data is a relationship of generator output versus generator efficiency. The generator condition includes a maximum generator output. This value is the maximum generator output the model will allow, assuming there is turbine capacity to meet this limit. The model will limit turbine output based on the generator maximum desired output. The generator efficiency curves for each of the units in the system are shown in Table 4-30 through Table 4-36.

Table 4-30. Bad Creek Development Units 1 through 4 Generator Efficiency Curve

4.6.6.4 Wicket Gate Leakage

The Wicket Gate Leakage flow is active only during times of non-generation. Thus, during periods of non-generation, this leakage flow is used to make up all or a portion of the minimum flow requirement. Wicket gate leakage is only modeled at the Jocassee and Keowee Stations, where it is 11 cfs per Jocassee unit and 25 cfs per Keowee unit for a total of 44 cfs and 50 cfs when no units are operating, respectively.

4.6.6.5 Powerhouse Weekend Operations

The Powerhouse Weekend Operations Condition permits the simulation of reduced powerhouse operations during Saturdays and/or Sundays. B ypass flow requirements are still met since bypass flows are not powerhouse dependent. Minimum instantaneous and minimum daily average flow requirements are met by bringing the powerhouse online for the required flow only. This condition removes the change-in-storage component from consideration in computing a desired daily discharge. To simulate actual usage, Saturday and Sunday powerhouse operations are minimized at the Keowee, Hartwell, and Richard B. Russell developments. During high inflow periods with little usable storage available, the model will bring the powerhouse online to generate with outflows, rather than permit spilling.

-22

4.6.6.6 Maintenance

The Maintenance schedule provides the functionality to take a unit out of service for all or part of each year for a scenario run. There are currently no outages modeled.

4.6.6.7 **Pump Efficiency**

The Pump Efficiency Condition provides the functionality to enter pump efficiency information for pumped storage plants. This dataset is required for plants with plant operation type specified as pumped storage and hybrid-pumped storage. The pump efficiency information modeled for the Bad Creek, Jocassee, and Richard B. Russell developments is presented in Table 4-37 through Table 4-39.

Table 4-37. Bad Creek Pump Efficiency

4.7 Bad Creek II Scenario

Bad Creek II scenario inputs are identical to the Baseline ("Base Case") scenario except for the following changes:

- Four additional units with the turbine efficiencies in Table 4-40, the generator efficiencies in Table 4-41, the pump efficiencies in Table 4-41, and the headlosses in Table 4-42, are available to meet energy requirements; and,
- The pump operations schedule was revised to reflect the availability of 8 units at Bad Creek due to the additional four units at Bad Creek II (Table 4-43).

^{*}Pumping unit operations are described with negative values.

4.8 Climate Sensitivities

Two water quantity sensitivity assessments were completed for the Baseline and Bad Creek II scenarios. These sensitivity assessments were simulated to evaluate possible impacts of future temperature increases and basin inflow reduction and were developed from climate change sensitivity scenarios identified during KT relicensing (HDR 2012b).

Climate change sensitivities CC-01 and CC-02 (as explained below) represent future possible climate change conditions. These two sensitivities are a simplification of possible future decreases in available water in the basin but were agreed upon by the OSC as a method to provide stakeholders with additional information to evaluate proposed operation scenarios during KT relicensing. The POR (January 1939 through December 31, 2011) plus the two climate change sensitivities represent the three hydrologic conditions discussed in this report.

4.8.1 Low Impact of Climate Change Sensitivity (CC-01 or ccLow)

The ccLow scenarios were simulated with a 3.0°Farenheit (°F) temperature increase, which was modeled as a 10 percent increase in natural surface evaporation and was developed based on the recommended CC-01 climate change scenario. The net impact was to simulate a reduction in available water in the basin due to increased surface evaporation applied uniformly over the entire 12 months of each year simulated. The application of the surface evaporation increase to the modeled net monthly evaporation coefficient included consideration of a positive or negative coefficient due to some months historically having more precipitation than evaporation. In the case of a negative monthly net evaporation coefficient, the adjustment was applied as to always result in less water being available in that reservoir.

4.8.2 High Impact of Climate Change Sensitivity (CC-02 or ccHigh)

The ccHigh scenarios were simulated with the addition of a 6.0°F temperature rise and a 10 percent decrease in incremental inflows to each reservoir. The 6.0°F increase in temperature was modeled as a 20 percent increase in natural surface evaporation (see explanation of application of increased evaporation in Section 4.8.1). The high impact climate change sensitivity was developed based on the recommended CC-02 climate change scenario (HDR 2014b)

4.9 Performance Measures

Performance Measures (PM) provide a means for relicensing stakeholders to readily distinguish between the outcomes of different scenarios. The PMs were initially developed by the OSC during KT relicensing. The PMs were generally retained for use during Bad Creek relicensing with minor modifications.

5 Modeled Results

5.1 Scenario Results

Elevation duration plots showing the detailed elevations for each scenario, for each reservoir, and for each of the three hydrologic conditions (Normal, ccLow, and ccHigh) are provided in Figure 5-1 through Figure 5-3. Discharge duration plots from Lake Keowee (discharge from the KT Project) are provided for each scenario and hydrologic condition in Figure 5-4. Performance Measure Sheets for each of the hydrologic conditions are provided in Appendix B. All simulated results presented in this report are based on the 15-minute model output, unless stated otherwise.

5.1.1 **Baseline (Current License)**

The Baseline scenario simulates reservoir operations by Duke Energy based on KT license requirements, including the LIP and 2014 Operating Agreement, and current Bad Creek License requirements. As demonstrated by the model results in Table 5-1 and the reservoir elevation duration curves in Figure 5-1through Figure 5-3, minimum and maximum reservoir elevations for Bad Creek Reservoir, Lake Jocassee, and Lake Keowee meet the FERC license normal minimum and maximum reservoir elevations for both the Project as well as the KT Project under the three hydrology conditions (i.e., Normal, ccLow and ccHigh). Simulated reservoir levels for the Bad Creek Reservoir, Lake Jocassee, and Lake Keowee were generally comparable under Normal and ccLow hydrology, but additional Bad Creek Reservoir storage was accessed for a short duration with the ccHigh hydrology. Simulated reservoir elevations under all three hydrology conditions maintain reservoir elevations at Lake Keowee higher than the minimum operating levels for the existing municipal water intakes and Oconee Nuclear Station. Bad Creek and the KT Project were simulated to be in some stage of the LIP approximately 67 to 70 percent

FDS

of the POR depending on the hydrology. Reservoir elevation duration curves are shown in Figure 5-1 through Figure 5-3.

Table 5-1. Minimum and Maximum Simulated Reservoir Elevations and Reservoir Operating Band for the Baseline Scenario (ft msl)

FDS

5.1.2 Bad Creek II

The Bad Creek II scenario is identical to the Baseline scenario except for the differences described in Section 4.7. As with the Baseline Scenario, the model results in Table 5-2 and Figure 5-1 through Figure 5-3 demonstrate minimum and maximum reservoir elevations for Bad Creek Reservoir, Lake Jocassee, and Lake Keowee meet the FERC license normal minimum and maximum reservoir elevations for both the Project as well as the KT Project under the three hydrology conditions (i.e., Normal, ccLow and ccHigh).

As with the Baseline scenario, simulated reservoir levels for the Bad Creek Reservoir, Lake Jocassee, and Lake Keowee were generally comparable under Normal and ccLow hydrology, but additional Bad Creek Reservoir storage was accessed with the ccHigh hydrology. Simulated reservoir elevations under all three hydrology conditions maintain reservoir elevations at Lake Keowee higher than the minimum operating levels for the existing municipal water intakes and Oconee Nuclear Station. The Project and the KT Project were simulated to be in some stage of the LIP 81 to 87 percent of the POR, depending on hydrology.

Table 5-2. Minimum and Maximum Simulated Reservoir Elevations for the Bad Creek II Scenario (ft msl)

ccHigh	791.4	799.1	800.0	8.6

6 Effects of Bad Creek II

Model results for the Baseline and Bad Creek II scenarios were compared to identify potential differences in the effects of Bad Creek II as contrasted with existing license conditions. This comparison is focused primarily on reservoir elevation effects.

As demonstrated by the modeling results, the effects of Bad Creek II are constrained by Duke Energy's continued compliance with the existing KT Project FERC license including the KT LIP and the 2014 Operating Agreement. These requirements would not be modified with the relicensing of the Project or the construction and operation of Bad Creek II, so little to no effects to the downstream USACE hydroelectric projects were identified in the model results.

The relative size differences between the Bad Creek Reservoir, Lake Jocassee, and Lake Keowee directly affect how generation and pumping volumes affect reservoir levels within the three reservoirs. As a general guide and ignoring all other inflows, withdrawals, downstream flow releases, and evaporation, a change of 1.0 ft of reservoir storage at the Bad Creek Reservoir results in 0.05 ft (0.6 inches) of change in Lake Jocassee's water level. If the same volume of water was then moved upstream or downstream at Jocassee, Lake Keowee's level would change by 0.02 ft (0.25 inches).

The following sections summarize key comparisons of modeling results for the Baseline and Bad Creek II scenarios. See Appendix B for the Performance Measures sheets for additional information regarding the modeled outcomes for the Project and KT Project.

6.1 Project and KT Project Reservoir Levels

Model results in Table 6-1 through Table 6-3 demonstrate an additional 8.4 ft to 21.4 ft, depending on hydrology, of storage at the Bad Creek Reservoir would be accessed under the Bad Creek II scenario as compared to the Baseline scenario. Depending on hydrology, effects on minimum reservoir levels at Lake Jocassee and Lake Keowee are less pronounced. As demonstrated by the reservoir elevation curves for Lake Jocassee and Lake Keowee (see Figure 5-2 and Figure 5-3), reservoir elevations under both scenarios are comparable. This is further demonstrated by the Performance Measures sheets in Appendix B. There are very few

differences in reservoir level-related measures when comparing the Baseline and Bad Creek II scenarios under all three hydrology conditions.

Both the Project and the KT Project normal minimum and normal maximum reservoir level limits in the existing Project license and the KT Project license would remain unchanged. As discussed above, reservoir elevations at Lake Keowee under the three hydrology conditions remain above the minimum reservoir operating levels for municipal water intakes and Oconee Nuclear Station, so no new effects to existing water intakes are anticipated.

Table 6-1. Normal Hydrology Minimum Simulated Reservoir Elevations Compared to the Baseline Scenario (ft msl)

Scenario	Bad Creek	Jocassee	Keowee
Baseline (Existing License)	2,246.1	1,084.1	791.6
Bad Creek II	2,224.7	1,084.5	791.6
Difference from Baseline	-21.4	0.4	0.0

Table 6-2. ccLow Sensitivity Minimum Simulated Reservoir Elevations Compared to the Baseline Scenario (ft msl)

Difference from Baseline	-8.4	-3.0	-0.6

6.1.1 Lake Level Fluctuations and Shoreline Erosion

6.1.1.1 Fluctuation Rates

Model results in Table 6-4 demonstrate the maximum reservoir fluctuation over a 24-hour window during the POR for both the Baseline and Bad Creek II scenarios. Figure 6-1 through Figure 6-3 show the variation in reservoir fluctuation over the POR for Bad Creek, Jocassee, and Keowee. Typically, about 60 percent of the time, the Bad Creek II scenario results in an approximately 15-foot increase in 24-hour fluctuation at Bad Creek as compared with the

Baseline scenario. In contrast, at Jocassee, about 97 percent of the time, the Bad Creek II scenario results in an approximately 0.4- to 0.2-ft decrease in 24-hour fluctuation as compared to the Baseline scenario. The decreased range in 24-hour fluctuations in Lake Jocassee is due to increased generation and pumping volumes associated with Bad Creek II. Both Bad Creek and Bad Creek II operations are synched with Jocassee Pumped Storage Station operations in the model such that both Bad Creek and Bad Creek II typically generate and pump when Jocassee generates and pumps. However, a larger volume of water moves between Bad Creek Reservoir and Lake Jocassee in the Bad Creek II scenario, offsetting more of the lake level fluctuation effects at Lake Jocassee caused by Jocassee Pumped Storage Station operations. The model indicates little to no difference in 24-hour fluctuations at Lake Keowee between the Bad Creek II scenario and the Baseline scenario.

The reduction in Jocassee reservoir elevation fluctuations for the Bad Creek II scenario is demonstrated by the Performance Measures related to spawning success. Under all three hydrology conditions, reservoir elevations are within a tighter fluctuation band compared to the Baseline scenario. At Lake Keowee, there are no significant differences in the spawning fluctuation bands. See Appendix B for the Performance Measures sheets.

Table 6-4. Normal Hydrology Maximum Simulated Reservoir Fluctuation Over 24-hours Compared to the Baseline Scenario (ft)

Scenario	Bad Creek	Jocassee	Keowee
Baseline (Existing License)	33.1	4.3	2.3
Bad Creek II	52.6	4.5	2.3
Difference from Baseline	19.2	0.2	0.0

Figure 6-2. Normal Hydrology Jocassee 24-hour Reservoir Fluctuation for 1939 – 2011

Figure 6-3. Normal Hydrology Keowee 24-hour Reservoir Fluctuation for 1939 – 2011

6.1.1.2 Whitewater River Cove Shoreline Erosion

As part of the Bad Creek II Feasibility Study authorized by Duke Energy, HDR developed a three-dimensional Computational Fluid Dynamic model for lower reservoir modeling to complement the Upper and Lower Reservoir Operational Impact Studies. This effort was carried out in support of evaluating a second inlet/outlet structure and the potential associated erosion impacts to the Whitewater River cove of Lake Jocassee. The final report "Lower Reservoir CFD Flow Modeling Report" was filed with the Bad Creek RSP as Appendix I in December 2022 (HDR 2022).

The results of the modeling indicate additional generation flows resulting from Bad Creek II would not increase erosion potential along the east bank (i.e., opposite bank) of the Whitewater River cove in Lake Jocassee across from the inlet/outlet structure assuming the geology is consistent along the eastern bank (i.e., bedrock). The modeled velocities were approximately equivalent to the physical model study velocities, which are representative of existing conditions. Flows from the existing configuration and operations have not resulted in erosion along the east

bank and velocities are within the general range compared to the proposed configuration; detailed results are included in HDR (2022).

6.1.1.3 Lake Jocassee Shoreline Erosion

To assess general characteristics of shoreline erosion along Lake Jocassee (and Lake Keowee), Duke Energy conducted a Shoreline Erosion Study (Baird 2013) during KT Project relicensing. The purpose of the erosion study was to determine the main drivers of shoreline erosion and to quantify erosion along the shorelines. The Baird (2013) study results showed sources of erosion include physical weathering (e.g., freeze-thaw), wave action from wind and recreational boating, concentrated runoff, non-project development along the shoreline (i.e., land development), and operation of the reservoir (cyclic raising and lowering lake levels). Results indicated the majority of shoreline erosion was caused by wave action associated with wind and boat wakes, and while water level fluctuations due to operations affected the elevations at which wave-induced erosion occurs, water level fluctuations themselves do not appear to contribute appreciably to the overall rate of shoreline erosion. Results indicated approximately 25 to 45 percent of the erosion noted was attributed to boat wakes in Lake Jocassee and the remainder was attributable to wind waves (Baird 2013). In general, wind and wave-caused erosion is expected to continue in areas with erodible soils where bedrock has not been exposed but may occur at higher or lower rates if pool elevations are modified (Baird 2013). Because the operating band for Lake Jocassee and Lake Keowee will not change with Bad Creek II operations, and CHEOPS modeling demonstrates the Lake Jocassee elevations will be generally consistent between the Baseline and Bad Creek II scenarios, the addition of Bad Creek II is not anticipated to affect erosion rates along the shorelines of Lake Jocassee.

Additionally, shoreline studies at Lake Jocassee including scarp height (thickness of soil visible above the water line), recession of banks, and percentage of shoreline protection around the reservoir, have been carried out (Orbis 2012). Overall, the study results showed approximately 75 percent of the Lake Jocassee shoreline is either (a) bedrock or (b) shows no signs of erosion (past or present) (Orbis 2012).

Duke Energy is responsible for managing activities within the reservoir boundaries of Lakes Jocassee and Keowee in a manner promoting safe public use and maintaining environmental safeguards. Duke Energy maintains a Shoreline Management Plan for Lakes Jocassee and

Keowee classifying the respective shorelines and denotes where environmentally important habitat exists, where existing facilities and uses occur, and where future/existing shoreline activities may be considered.

6.1.2 **Aquatic Resources**

Potential effects to aquatic resources in Lake Jocassee related to changes in water level fluctuation and exchange of water between the upper and lower reservoirs are considered in the Aquatic Resources Study Report (Task 2 – Effects of Bad Creek II Complex and Expanded Weir on Aquatic Habitat).

6.1.3 LIP Stages

The percent of days in some stage of the LIP increased under all three hydrology conditions (Normal, ccLow and ccHigh) when comparing Bad Creek II with the Baseline scenario. The various LIP stages are triggered by the ratio of storage in the Duke Energy reservoirs compared to the storage in the USACE reservoirs. The addition of Bad Creek II results in increased (simulated) flow releases from Keowee, which in turn creates reservoir storage imbalances between the Duke Energy and USACE reservoirs. This effect is slightly more pronounced under the ccHigh hydrologic conditions. While these incremental changes in reservoir storage balance are small between the Duke Energy and USACE reservoirs (i.e., typically less than 1.5 percent), they are oftentimes enough to trigger the next LIP stage. As a result, the Bad Creek II scenario results in a shift of days from "normal" (i.e., non-drought stage) to LIP Stage 0 (the first drought stage), as shown on Figure 6-4. Likewise, there are a few occurrences where there is a similar shift in days from one LIP Stage to the next9. In reality, these shifts may not occur, or the frequency of occurrence may be less, due to real-time operations which would likely limit excess flow releases from Keowee during drought conditions. As a result, the number of days in any LIP stage may be less than what is depicted on Figure 6-4.

⁹ See Performance Measures 64 through 69 in Appendix B which demonstrate the shifting of days between the earliest LIP stages.

Figure 6-4. Days in KT LIP Stages for 1939 - 2011

6.2 Effects on USACE Reservoirs

The Water Resources Study Plan identified the geographic extent of the CHEOPS task as Lake Jocassee and Lake Keowee. However, FERC identified the geographic scope of the cumulative effects analysis for water resources as the Savannah River to its mouth. To support this evaluation, CHEOPS results for the three downstream USACE reservoirs were reviewed to identify differences in the timing and magnitude of flow releases from Keowee into Lake Hartwell, the most upstream USACE reservoir.

As discussed above, both the Baseline and Bad Creek II scenarios include continued compliance with the existing KT FERC license including implementation of the KT LIP and the 2014 Operating Agreement. These requirements limit the potential effects of Project operations and Bad Creek II proposed operations on the USACE reservoirs. As shown in Table 6-5, average annual downstream flow releases from the Keowee Development under both scenarios are identical under Normal and ccLow hydrology; using the ccHigh hydrology, differences are less than one percent. Consequently, the average annual releases from the J. Strom Thurmond

Development are identical for both scenarios using Normal and ccLow hydrology and differ by only 0.1 percent under ccHigh hydrology.

Table 6-5. Average Annual Flow Releases from the Keowee and J. Strom Thurmond Developments for the Baseline and Bad Creek II Scenarios 1939 – 2011 (cfs)

	Keowee	Average Ann	ual Release	J. Strom Thurmond Average Annual					
Uvdnology		(cfs)		Release (cfs)					
Hydrology	Baseline	Bad Creek	Change	Baseline	Bad Creek	Change			
	Daseillie	II	(%)	Daseillie	II	(%)			
Normal	944	944	0	7,719	7,719	0			
ccLow	939	939	0	7,680	7,680	0			
ccHigh	829	837	0.9	6,825	6,833	0.1			

The timing of downstream releases is also tightly aligned as demonstrated by an evaluation of the total cumulative volume of water released downstream of the Keowee Development and J. Strom Thurmond for the POR (Figure 6-5). Given these findings, few if any effects on the USACE reservoirs are anticipated.

Figure 6-5. Keowee and J. Strom Thurmond Cumulative Release for 1939 – 2011 under Normal, ccLow, and ccHigh hydrology (total volume, thousand acre-ft [TAF])

7 Conclusions

Reviewing the results of the Baseline and Bad Creek II scenarios leads to the following observations:

- Additional reservoir storage at the Bad Creek Reservoir would be accessed with Bad
 Creek II operations as compared to operations under the Baseline scenario.
- Lake Jocassee reservoir level fluctuations over a 24-hour period would generally be smaller than would occur under the Baseline scenario. The 24-hour fluctuations would be

two feet or less approximately 90% of the time under the Bad Creek II scenario, but only 75% of the time under the Baseline Scenario.

- The effects of the proposed Bad Creek II on lake level fluctuations at Lake Keowee and would be comparable to the effects of Bad Creek. There is no significant long-term difference between reservoir elevations including reservoir level range or reservoir level fluctuation frequencies.
- Proposed Bad Creek II operations have no modeled effect on municipal water intakes on Lake Keowee or Oconee Nuclear Station.
- KT LIP Stage 0 would be triggered more frequently with Bad Creek II, but the differences in KT LIP stage frequencies generally diminish in the more advanced stages of the KT LIP.
- Proposed Bad Creek II operations have little to no modeled effects on the downstream USACE reservoirs or flow releases into the Savannah River.

8 Need for Protection, Mitigation, and **Enhancement Measures to Protect Water** Quality

Based on the results of CHEOPS modeling, and in consideration of results of other data collection efforts in support of KT relicensing (Duke Energy 2014), there is no need for additional PM&E measures to address reservoir elevation changes or downstream flow releases to the USACE reservoirs.

9 Variances from FERC-approved Study Plan

There were no variances from the FERC-approved RSP for this task of the Water Resources Study except for the addition of additional evaluation of the potential lake levels at the USACE reservoirs and flow releases downstream of the Project.

Number	Lake Jocassee	,			(Note 2)	(1939-2011)	(1939-2011)
	Elevation - Storage Availability						
1	Maximize adherence to reliably meet all Project-related water demands Elevation - Recreation	Number of years reservoir level at or above 1,108 ft AMSL on May 1	1-May	1-May	5	0	0
2	Lievalion - Neorealion	Number of years where cove access (reservoir level below 1,090 ft AMSL) is restricted for more than 25 days (Note 3)	1-Jan	31-Dec	2	2	2
3	Minimize restricted recreation	Greatest number of days with restricted cove access (reservoir level below 1,090 ft AMSL) during higher use months in any calendar year (Note 3)	1-Mar	31-Oct	5	43	43
4		Greatest number of days with restricted cove access (reservoir level below 1,090 ft AMSL) in any calendar year (Note 3)	1-Jan	31-Dec	5	104	104
5	Minimize restricted boat launching	Number of years where reservoir level is below boat ramp critical level (1,080 ft AMSL) during higher use months for more than 25 days (Note 4)	1-Mar	31-Oct	2	0	0
6		Greatest number of days where reservoir level is below boat ramp critical level (1,080 ft AMSL) during higher use months in any calendar year (Note 4)	1-Mar	31-Oct	5	0	0
7	Minimize effects on recreational boating Elevation - Natural Resources	Number of days where reservoir level changes more than 1.0 ft in one hour	1-Jan	31-Dec	10	0	0
8	Elevation - Natural Resources	Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 10 consecutive days at least once (Note 5)	1-Apr	31-May	5%	71%	100%
9		Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 15 consecutive days at least once (Note 5)	1-Apr	31-May	5%	34%	99%
10	Maximize spawning success for black bass and blueback herring (2.5-ft fluctuation band)	Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 20 consecutive days at least once (Note 5)	1-Apr	31-May	5%	19%	89%
11	(2.5-it iluctuation band)	Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 30 consecutive days at least once (Note 5)	1-Apr	31-May	5%	0%	59%
12		Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 45 consecutive days at least once (Note 5)	1-Apr	31-May	5%	0%	0%
13		Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band for 10 consecutive days at least once (Note 5)	1-Apr	31-May	5%	100%	100%
14		Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band for 15 consecutive days at least once (Note 5)	1-Apr	31-May	5%	100%	100%
15	Maximize spawning success for black bass and blueback	Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band	1-Apr	31-May	5%	100%	99%
16	herring (3.5-ft fluctuation band)	for 20 consecutive days at least once (Note 5) Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band for 30 consecutive days at least once (Note 5)	1-Apr	31-May	5%	95%	97%
17		Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band for 45 consecutive days at least once (Note 5)	1-Apr	31-May	5%	56%	82%
18	Maximize spawning success for sunfish and	Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 10 consecutive days at least once (Note 5)	15-May	15-Jul	5%	45%	100%
19	threadfin shad (2.5-ft fluctuation band)	Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 15 consecutive days at least once (Note 5)	15-May	15-Jul	5%	14%	92%
20	(200 11 10 10 10 10 10 10 10 10 10 10 10 1	Percent of years (hourly) reservoir level remains within (-0.5 to 2.0)-ft band for 20 consecutive days at least once (Note 5) Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band	15-May	15-Jul	5%	0%	3%
21	Maximize spawning success for sunfish and	for 10 consecutive days at least once (Note 5)	15-May	15-Jul	5%	100%	100%
22	threadfin shad (3.5-ft fluctuation band)	Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band for 15 consecutive days at least once (Note 5) Percent of years (hourly) reservoir level remains within (-0.5 to 3.0)-ft band	15-May	15-Jul	5%	100%	100%
23		for 20 consecutive days at least once (Note 5)	15-May	15-Jul	5%	79%	99%
24	Minimize entrainment due to Bad Creek operations	Percent of days average reservoir level at or below 1,096 ft AMSL (Note 6) Percent of days average reservoir level below 1,096 ft AMSL (Note 6)	1-Jan 1-Dec	31-Dec 	5%	2%	2%
26	Advisor like and balance during a constraint	Percent of days average reservoir level above 1,107 ft AMSL (Note 7)	1-Apr	30-Sep	5%	46%	42%
27	Maximize littoral habitat during growing season	Percent of days average reservoir level above 1,105 ft AMSL (Note 7)	1-Apr	30-Sep	5%	91%	91%
28	Maximize littoral habitat during spawning	Percent of days average reservoir level above 1,107 ft AMSL (Note 7)	1-Apr	31-May	5%	20%	16%
29	season	Percent of days average reservoir level above 1,105 ft AMSL (Note 7)	1-Apr	31-May	5%	92%	92%
30	Pumped Storage Minimize days below lake levels that impact	Number of days reservoir level below 1,099 ft AMSL (Note 8)	1-Jan	31-Dec	227	846	804
31	Bad Creek operations Minimize days below lake levels that impact	Number of days reservoir level below 1,090 ft AMSL (Note 8)	1-Jan	31-Dec	14	147	139
32	Jocassee operations Minimize days below lake levels that impact	Number of days reservoir level below 1,081 ft AMSL (Note 9)	1-Jan	31-Dec	12	0	0
32	Bad Creek efficiency Lake Keowee	Number of days reservoir level below 1,001 it Aivise (Note 5)	1 3011	31 Dec	12	0	<u> </u>
	Elevation - Storage Availability						
33	Maximize adherence to reliably meet all Project-related water demands Elevation - Aesthetics	Number of years reservoir level at or above 798 ft AMSL on May 1	1-May	1-May	5	69	69
34 35	Maximize lake levels	Percent of time reservoir level at or above 797 ft AMSL Percent of time reservoir level at or above 795 ft AMSL	1-Jan 1-Jan	31-Dec 31-Dec	20% 10%	91% 97%	92% 97%
36	Minimize significant drawdown of lake level	Number of days reservoir level below 796 ft AMSL	1-Jan	31-Dec	5	1,670	1,608
37	Elevation - Recreation	Number of years where cove access (reservoir level below 792 ft AMSL) is restricted for more than 25 days (Note 10)	1-Jan	31-Dec	2	1	1
38	Minimize restricted recreation	Greatest number of days with restricted cove access (reservoir level below 792 ft AMSL) during higher use months in any calendar year (Note 10)	1-Mar	31-Oct	5	1	1
39		Greatest number of days with restricted cove access (reservoir level below 792 ft AMSL) in any calendar year (Note 10)	1-Jan	31-Dec	5	41	41
40		Number of years where reservoir level is below boat ramp critical level (790 ft AMSL) during higher use months for more than 25 days (Note 11)	1-Mar	31-Oct	2	0	0
41	Minimize restricted lake boat launching	Greatest number of days where reservoir level is below boat ramp critical level (790 ft AMSL) during higher use months in any calendar year (Note 11)	1-Mar	31-Oct	5	0	0
42		Percent of time reservoir level is at or above level where 85% of docks are usable (796.25 ft AMSL) during higher use months from 7:00 am to 7:00 pm	1-Mar	31-Oct	5%	94%	94%
43	Maximize boat dock usage	(Note 12) Percent of time reservoir level is at or above level where 70% of docks are usable (793.5 ft AMSL) during higher use months from 7:00 am to 7:00 pm	1-Mar	31-Oct	5%	99%	99%
		(Note 12)	2	32 000		33/0

68		Number of days in LIP Stage 3	1-Jan	31-Dec		378	378
69		Number of days in LIP Stage 4	1-Jan	31-Dec		49	49

Background	Performance Measure has improved vs. the Baseline Scenario
Background	Performance Measure has declined vs. the Baseline Scenario
White Background	There is no significant difference between the scenario and the Baseline Scenario by definition of MISC

Notes	
	For criterion that measure on an hourly or daily basis, unless stated otherwise:
1	a. If an hourly criteria occurs during the average of four contiguous 15-minute periods, then it counts as 1 hour.
1	b. If a daily criterion occurs for 5 contiguous 1-hour periods, then it counts as 1 day.
	Also, daytime flows are assumed to be flows provided between 7:00 am and 7:00 pm. To the extent possible, each criterion is defined in terms of percents and averages/yr so that the same criterion is useful
	MISC = Minimum Increment of Significant Change. The MISC has the same units (i.e., days, days/yr, percent, etc.) as does the criterion on that same row of the spreadsheet. If the output of two scenarios for a
2	a. As a general rule, MISC numbers are set at 10% of the possible total for that criterion considering the Start/Stop dates.
2	b. MISC numbers for criteria that have the most adverse outcomes if reached are typically set at less than 10% of the possible total for that criterion.
	c. Adjustments to the MISC numbers (up or down) have also been made depending on the desires of the stakeholders that primarily have the interests that are being measured by a particular criterion.
3	Jocassee restricted recreation elevation 1,090 ft AMSL provided by Chris Starker (Upstate Forever) and confirmed by Devils Fork State Park Staff.
4	Jocassee elevation 1,077 ft AMSL is the lowest boat ramp elevation with an additional 3 ft added for boat access. Boat ramp elevations provided by Duke Energy.
5	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.
6	Jocassee entrainment elevation (1,096 ft AMSL) provided by Bill Marshall of SCDNR.
7	Jocassee fish habitat elevations provided by Bill Marshall of SCDNR.
8	Jocassee elevation 1,099 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is
9	Jocassee elevation 1,081 ft AMSL provided by Duke Energy based on impact to pumping equipment.
10	Keowee restricted recreation elevation of 792 ft AMSL provided by James McRacken (HDR) and Scott Fletcher (Duke Energy).
11	Keowee elevation 790 ft AMSL is based on the lowest boat ramp elevation of 787 ft AMSL plus 3 ft for boat access (provided by Duke Energy).
12	Percent of time is measured as the percent of 15-minute time steps at or above threshold elevation during period starting 07:00 am and period ending 7:00 pm.
13	Toe of Keowee reservoir riprap elevation 794 ft AMSL provided by Duke Energy.
14	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.
15	Keowee fish habitat elevations provided by Bill Marshall of SCDNR.
16	Keowee elevation 775 ft AMSL was the minimum level permitted in the previous KT FERC License, and the Keowee water supply intakes present during KT relicensing were confirmed to operate at this
	For this measure a -0.5 ft buffer was added to filter out model excursions below the Keowee reservoir elevation limit of 790.0 ft AMSL. No counts will be displayed for reservoir levels between 789.5 ft AMSL
17	and 790.0 ft AMSL for this measure.
18	Keowee elevation 787.9 ft AMSL is the critical elevation for Keowee to provide backup power to ONS elevation provided by Duke Energy.
19	There are 26,663 days in the POR.

Background	Performance Measure has improved vs. the Baseline Scenario
Background	Performance Measure has declined vs. the Baseline Scenario
White Background	There is no significant difference between the scenario and the Baseline Scenario by definition of MISC

Notes	
	For criterion that measure on an hourly or daily basis, unless stated otherwise:
1	a. If an hourly criteria occurs during the average of four contiguous 15-minute periods, then it counts as 1 hour.
1	b. If a daily criterion occurs for 5 contiguous 1-hour periods, then it counts as 1 day.
	Also, daytime flows are assumed to be flows provided between 7:00 am and 7:00 pm. To the extent possible, each criterion is defined in terms of percents and averages/yr so that the same criterion is useful regardless of the
	MISC = Minimum Increment of Significant Change. The MISC has the same units (i.e., days, days/yr, percent, etc.) as does the criterion on that same row of the spreadsheet. If the output of two scenarios for a particular
2	a. As a general rule, MISC numbers are set at 10% of the possible total for that criterion considering the Start/Stop dates.
	b. MISC numbers for criteria that have the most adverse outcomes if reached are typically set at less than 10% of the possible total for that criterion.
	c. Adjustments to the MISC numbers (up or down) have also been made depending on the desires of the stakeholders that primarily have the interests that are being measured by a particular criterion.
3	Jocassee restricted recreation elevation 1,090 ft AMSL provided by Chris Starker (Upstate Forever) and confirmed by Devils Fork State Park Staff.
4	Jocassee elevation 1,077 ft AMSL is the lowest boat ramp elevation with an additional 3 ft added for boat access. Boat ramp elevations provided by Duke Energy.
5	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.
6	Jocassee entrainment elevation (1,096 ft AMSL) provided by Bill Marshall of SCDNR.
7	Jocassee fish habitat elevations provided by Bill Marshall of SCDNR.
8	Jocassee elevation 1,099 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is the elevation at which are supported by the support of the suppor
9	Jocassee elevation 1,081 ft AMSL provided by Duke Energy based on impact to pumping equipment.
10	Keowee restricted recreation elevation of 792 ft AMSL provided by James McRacken (HDR) and Scott Fletcher (Duke Energy).
11	Keowee elevation 790 ft AMSL is based on the lowest boat ramp elevation of 787 ft AMSL plus 3 ft for boat access (provided by Duke Energy).
12	Percent of time is measured as the percent of 15-minute time steps at or above threshold elevation during period starting 07:00 am and period ending 7:00 pm.
13	Toe of Keowee reservoir riprap elevation 794 ft AMSL provided by Duke Energy.
14	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.
15	Keowee fish habitat elevations provided by Bill Marshall of SCDNR.
16	Keowee elevation 775 ft AMSL was the minimum level permitted in the previous KT FERC License, and the Keowee water supply intakes present during KT relicensing were confirmed to operate at this reservoir level.
	For this measure a -0.5 ft buffer was added to filter out model excursions below the Keowee reservoir elevation limit of 790.0 ft AMSL. No counts will be displayed for reservoir levels between 789.5 ft AMSL and 790.0 ft AMSL
17	for this measure.
18	Keowee elevation 787.9 ft AMSL is the critical elevation for Keowee to provide backup power to ONS elevation provided by Duke Energy.
19	There are 26,663 days in the POR.

Background	Performance Measure has improved vs. the Baseline Scenario
Background	Performance Measure has declined vs. the Baseline Scenario
White Background	There is no significant difference between the scenario and the Baseline Scenario by definition of MISC

Notes	
Notes	For criterion that measure on an hourly or daily basis, unless stated otherwise:
1	
	a. If an hourly criteria occurs during the average of four contiguous 15-minute periods, then it counts as 1 hour.
	b. If a daily criterion occurs for 5 contiguous 1-hour periods, then it counts as 1 day.
	Also, daytime flows are assumed to be flows provided between 7:00 am and 7:00 pm. To the extent possible, each criterion is defined in terms of percents and averages/yr so that the same criterion is useful regardless of the length
	MISC = Minimum Increment of Significant Change. The MISC has the same units (i.e., days, days/yr, percent, etc.) as does the criterion on that same row of the spreadsheet. If the output of two scenarios for a particular criterion
2	a. As a general rule, MISC numbers are set at 10% of the possible total for that criterion considering the Start/Stop dates.
	b. MISC numbers for criteria that have the most adverse outcomes if reached are typically set at less than 10% of the possible total for that criterion.
	c. Adjustments to the MISC numbers (up or down) have also been made depending on the desires of the stakeholders that primarily have the interests that are being measured by a particular criterion.
3	Jocassee restricted recreation elevation 1,090 ft AMSL provided by Chris Starker (Upstate Forever) and confirmed by Devils Fork State Park Staff.
4	Jocassee elevation 1,077 ft AMSL is the lowest boat ramp elevation with an additional 3 ft added for boat access. Boat ramp elevations provided by Duke Energy.
5	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.
6	Jocassee entrainment elevation (1,096 ft AMSL) provided by Bill Marshall of SCDNR.
7	Jocassee fish habitat elevations provided by Bill Marshall of SCDNR.
8	Jocassee elevation 1,099 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is the elevation at
9	Jocassee elevation 1,081 ft AMSL provided by Duke Energy based on impact to pumping equipment.
10	Keowee restricted recreation elevation of 792 ft AMSL provided by James McRacken (HDR) and Scott Fletcher (Duke Energy).
11	Keowee elevation 790 ft AMSL is based on the lowest boat ramp elevation of 787 ft AMSL plus 3 ft for boat access (provided by Duke Energy).
12	Percent of time is measured as the percent of 15-minute time steps at or above threshold elevation during period starting 07:00 am and period ending 7:00 pm.
13	Toe of Keowee reservoir riprap elevation 794 ft AMSL provided by Duke Energy.
14	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.
15	Keowee fish habitat elevations provided by Bill Marshall of SCDNR.
16	Keowee elevation 775 ft AMSL was the minimum level permitted in the previous KT FERC License, and the Keowee water supply intakes present during KT relicensing were confirmed to operate at this reservoir level.
	For this measure a -0.5 ft buffer was added to filter out model excursions below the Keowee reservoir elevation limit of 790.0 ft AMSL. No counts will be displayed for reservoir levels between 789.5 ft AMSL and 790.0 ft AMSL for
17	this measure.
18	Keowee elevation 787.9 ft AMSL is the critical elevation for Keowee to provide backup power to ONS elevation provided by Duke Energy.
19	There are 26,663 days in the POR.

WQMP or Plan Bad Creek II Complex Water Quality Monitoring Plan

1 Project Introduction

Duke Energy Carolinas, LLC (Duke Energy or Licensee) is the owner and operator of the 1,400-megawatt Bad Creek Pumped Storage Project (Project) (FERC Project No. 2740) located in Oconee County, South Carolina, approximately eight miles north of Salem. The Project utilizes the Bad Creek Reservoir as the upper reservoir and Lake Jocassee, which is licensed as part of the Keowee-Toxaway Hydroelectric Project (KT Project; FERC Project No. 2503), as the lower reservoir.

The existing (original) license for the Project was issued by the Federal Energy Regulatory Commission (FERC or Commission) for a 50-year term, with an effective date of August 1, 1977, and expires July 31, 2027. The license has been subsequently and substantively amended, with the most recent amendment on August 6, 2018 for authorization to upgrade and rehabilitate the four pump-turbines in the powerhouse and increase the Authorized Installed and Maximum Hydraulic capacities for the Project. ¹

Given the need for additional significant energy storage and renewable energy generation across Duke Energy's service territories over the Project's new 40 to 50-year license term, Duke Energy is evaluating opportunities to add pumping and generating capacity at the Project. Additional energy storage and generation capacity would be developed by constructing a new power complex (including a new underground powerhouse) adjacent to the existing Bad Creek powerhouse. Therefore, construction of the 1,400-megawatt Bad Creek II Power Complex (Bad Creek II or Bad Creek II Complex) is an alternative relicensing proposal presently being evaluated by Duke Energy.

¹ Duke Energy Carolinas LLC, 164 FERC ¶ 62,066 (2018)

2 Plan Description and Format

The development of the Bad Creek II Complex and construction activities associated with the new facility components could result in temporary and permanent impacts to water resources at the Project. As part of the relicensing studies, Duke Energy proposed to develop a Water Quality Monitoring Plan (WQMP or Plan) in consultation with agencies focused on water quality impacts associated with the Bad Creek II Complex as part of the new license. Development of this plan was described in the Revised Study Plan filed with the Commission in accordance with 18 CFR §5.15 and was listed as one of the protection, mitigation, and enhancement (PM&E) measures for potential impacts in the Pre-Application Document (Duke Energy 2022):

 Development of a Water Quality Monitoring Plan in consultation with agencies, including monitoring locations, methods, and reporting criteria for major parameters such as DO, temperature, pH, specific conductance, and turbidity for Project construction (pre-, during, and post-construction) and operation.

The WQMP considers water quality and monitoring methods in the Whitewater River cove of Lake Jocassee as well as stream conditions in upland areas that will potentially be affected by Bad Creek II construction activities. Site-specific monitoring prior to Bad Creek II construction (i.e., pre-construction phase), during construction (i.e., construction phase), and following construction (i.e., post-construction) to document operational conditions is proposed.

This Plan describes two different monitoring strategies to assess Project waters depending on location (i.e., Lake Jocassee vs. upland areas). As further discussed in Section 5, select water quality parameters in the Whitewater River cove of Lake Jocassee will be measured via a multiparameter sonde, while upland surface waters will be monitored downstream of impacted areas via stream habitat quality surveys. These stream assessments will consider stream conditions, aquatic resources, and habitat function and will be supported by routine monitoring of storm events and best management practices (BMPs), which will be developed and implemented though the Erosion and Sediment Control (ESC) permitting process (i.e., National Pollutant Discharge Elimination System [NPDES] for Construction Stormwater). Efforts carried out during Plan development will also aid information gathering in support of Clean Water Act (CWA) 404/401 permitting related to potential impacts to surface waters downstream from

upland spoil locations as well as potential impacts to Lake Jocassee from construction activities and proposed submerged weir expansion.

This Plan presents relevant background information, objectives, monitoring rationale, and methods for monitoring. A separate Standard Operating Procedures (SOP) document will be developed following issuance of a joint U.S. Army Corps [USACE] CWA 404/401 permit for construction of Bad Creek II. The SOP will include detailed aspects of field monitoring including sampling locations and maps, sampling methods, instrumentation specifications, and field data collection forms. The SOP will provide procedures for consistent and scientifically valid quantitative and qualitative monitoring in support of water and aquatic resources for Bad Creek II Complex construction.

3 Objectives

Development of the WQMP was proposed as Task 5 of the Water Resources Study (*Future Water Quality Monitoring Plan Development*) and was developed in consultation with agencies and stakeholders. It is intended to provide sufficient information to support an analysis of the potential Project-related effects on water resources with nexus to the Project and proposed Bad Creek II Complex. The WQMP focuses on the proposed Bad Creek II Complex with the main goal of identifying applicable water quality parameters and/or surface water conditions to monitor associated with construction as well as appropriate monitoring methods for compliance with the South Carolina Department of Environmental Services (SCDES)² regulations and protection of existing uses.

² SCDES was established on July 1, 2024, when the South Carolina Department of Health and Environmental Control (SCDHEC) became two separate agencies.

4 Project Background

The Project is located in the Blue Ridge physiographic province in the headwaters of the Savannah River basin. The Savannah River basin has an area of approximately 10,577 square miles (mi²) and drains portions of the Blue Ridge, Piedmont, and Coastal Plain regions.

The Project uses the Bad Creek Reservoir as its upper reservoir, which has a drainage area of approximately 1.5 mi². Construction of the Project began in December 1985 and major work was completed by December 1990; initial filling of the Bad Creek Reservoir began in January 1991. Prior to impoundment, Bad Creek and West Bad Creek were tributaries of Howard Creek (a tributary to Lake Jocassee) located near the toe of the Main Dam and West Dam, respectively. Howard Creek flows from its headwaters (northwest of the Project) and through the southern border of the Project Boundary with a drainage area of approximately 4.3 mi² at its downstream confluence with Limber Pole Creek. Seepage through the two earthen dams now flows into Howard Creek near the toe of each dam. Average seepage flows from the Main Dam and the West Dam are approximately 5.0 cubic feet (ft) per second combined. Water from Bad Creek Reservoir is exchanged directly with Lake Jocassee. Due to the small drainage area of Bad Creek Reservoir, inflows are minimal and have limited to no effect on water quality or Project operations.

Lake Jocassee, which operates as the lower reservoir for the Project, was formed by impounding the Keowee River at river mile 343.6, just downstream of the confluence of the Whitewater and Toxaway rivers. Lake Jocassee has a drainage area of 145 mi², a surface area of approximately 7,980 acres, and approximately 92 miles of shoreline at full pond (1,110 ft above mean sea level [msl]). Water from Lake Jocassee flows directly into Lake Keowee, which was formed by impounding the Keowee River and the Little River.

During Project construction, excavated rockfill was hauled to the western shore of Whitewater River cove (also called Whitewater River arm), transported out into the lake on barges, and placed in the water to construct an underwater weir approximately 1,800 ft downstream of the Project inlet/outlet (I/O) structure (weir midpoint lat/long coordinates 35.0015, -82.991509). The existing submerged weir is approximately 567 ft wide and 455 ft long with a crest elevation of approximately 1,060 ft msl. It was constructed to help minimize the effects of Project operations

FD3

on the natural stratification of Lake Jocassee downstream of the weir and dissipate the energy of the discharging water from the Project's I/O structure. Duke Energy is proposing to expand the existing submerged weir in the downstream direction (weir crest will have same elevation) with newly excavated rockfill from the proposed Bad Creek II Complex. Results of recent modeling efforts in the Whitewater River cove indicate stratification is maintained downstream of the proposed expanded weir similar to current conditions.³

4.1 Original License Requirements

As a condition of the Original License for the Project, Duke Energy entered into a Memorandum of Understanding (MOU) with the South Carolina Department of Natural Resources (SCDNR) for the long-term management and maintenance of high-quality fishery resources in Lake Keowee, Lake Jocassee, and their tributary streams (Duke Power and SCDNR 1996). The MOU called for successive 10-Year Work Plans⁴ (i.e., 1996 – 2005; 2006 – 2015; and 2017 – 2027). Each Work Plan identifies specific management activities, funding initiatives, and communications protocols which both Duke Energy and SCDNR believe are important to the effective management of the KT area's fishery resources.

Major PM&E measures for original Project construction as well as ongoing Project operation were primarily focused on fisheries, water quality, and recreation, and are established by the following:

- Bad Creek Project License Exhibit S (Environmental Study Plans)⁵
- Duke Energy and SCDNR MOU and 10-Year Work Plans
- KT Project Relicensing Agreement
- Recreation Plan (Exhibit R)

³ Three-dimensional Computational Fluid Dynamics modeling methods and results are included in final report *Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse* filed with the Initial Study Report. Available at FERC eLibrary: https://elibrary.ferc.gov/eLibrary/filelist?accession_num=20240104-5044.

⁴ The first two Ten-Year Work Plans were titled "Keowee-Toxaway Fishery Resources Work Plan." However, several activities conducted under these work plans were identified as PM&E measures for the KT Project and were included in the KT Relicensing Agreement. As a result, those measures were not included in the 2017-2027 Work Plan and it is now titled "Bad Creek Fishery Resources Work Plan."

⁵ License Article #32 (as amended on May 2, 1978, August 15, 1979, and October 2, 1995) required Duke Energy to file a revised Exhibit S within one year of license issuance to address fish and wildlife PM&E measures.

The MOU and first 10-Year Work Plan were approved pursuant to Article 32(b)(1) of the license for the Bad Creek Project on May 1, 1997. Activities included in the 10-Year Work Plans are focused on fisheries surveys and inventories, water quality and aquatic habitat evaluations, fish stocking, recreation, and shoreline impacts. Several activities under the 10-Year Work Plans were later identified as PM&E measures appropriate for transfer to the KT Project and are now addressed under the KT Project Relicensing Agreement associated with the FERC license issued in 2016. These included an agreement on measures to reduce fish entrainment at the Jocassee Pumped Storage Station, an agreement to maintain pelagic trout habitat in Lake Jocassee, and an agreement to maintain the lower Eastatoe Creek angler access area, as well as a requirement to monitor dissolved oxygen (DO) concentrations in the tailwaters of the Jocassee and Keowee Developments each August for the term of the KT Project license to demonstrate compliance with South Carolina's water quality standards regulated by SCDES.

The current 10-Year Work Plan continues many of the management activities implemented in prior work plans. The current Work Plan is composed of five main elements and will continue until 2027:

- 1. agreement on minimizing fish entrainment via the Project;
- 2. hydroacoustic monitoring of small pelagic fish;
- 3. electrofishing of littoral fish populations;
- 4. cost sharing for trout stocking; and
- 5. cost sharing for fisheries research and enhancements.

Duke Energy's trout habitat monitoring program addresses two different license articles for the Bad Creek Project. License Article #32(b)(2) covers Lake Jocassee pelagic trout habitat and License Article #34 covers Lake Jocassee water quality (both articles required Duke Energy to conduct a water quality and trout habitat monitoring program for a 5-year period (i.e., 1995 – 1999)⁶ to capture conditions upon Project start-up.

⁶ The pelagic trout habitat monitoring program in Lake Jocassee began in 1973 to coincide with operations at the Jocassee Pumped Storage Station. Under the existing monitoring program, if trout habitat is projected to be less than 10 meters thick (based on water temperatures and DO concentrations) by September of each year, Duke Energy will measure water temperature and DO in June and August to monitor thickness, as well as consult with SCDNR regarding potential modifications to hydropower operations; however, this situation has yet to arise based on monitoring. This condition has never been triggered during the Original License term.

Although Lake Jocassee water quality meets all state water quality standards, SCDES's water quality certification (CWA Section 401; SCDHEC 1995) requires Duke Energy to monitor DO, therefore, this parameter (as well as temperature) is still routinely monitored in the Keowee Hydro Station and Jocassee Pumped Storage Station tailwaters. In 2008, Duke Energy installed water quality monitors (temperature, DO, conductivity, and water level) in the tailraces of both Jocassee and Keowee hydroelectric stations. A summary of data is included in Section 6.3 of the Pre-Application Document (Duke Energy 2022).

As indicated above, activities associated with water quality monitoring in Lake Jocassee (trout habitat, DO and temperature monitoring) will continue throughout the remainder of the KT Project license term, which extends until August 31, 2046.

4.2 Historic Water Quality Monitoring

Bad Creek Reservoir is used only for Project operations; it is not designated for any other uses and therefore has no applicable state or federal water quality standards. While there are no state or federal water quality standards applicable to the waters of the upper reservoir, Lake Jocassee is included in the highest water quality classification (i.e., excellent rating) as designated by SCDES and preservation of existing conditions is recommended, with most tributaries within the watershed fully supporting their designated uses. Lake Jocassee is one of only a few reservoirs in South Carolina that possesses the necessary aquatic habitat (water temperature and DO) to support both a warmwater and a coldwater (salmonid [trout]) fishery year-round (USACE 2014) and Duke Energy has monitored water quality conditions in Lake Jocassee since its formation (1974). Streams affected by the original construction of the Project include Bad Creek and West Bad Creek, which were dammed to create the upper reservoir, and Howard Creek, which flows immediately downstream of the Project's main dam and enters Lake Jocassee.

As part of the ongoing relicensing effort for the Project, Duke Energy carried out a comprehensive desktop analysis of historic water quality in Lake Jocassee that included DO concentration, DO saturation, water temperature, conductivity, phosphorus, and nitrogen data from 12 water quality monitoring stations. Data were compared between pre-Project and post-Project operations. Turbidity values (vertical profiles) were also assessed at the three Whitewater River cove locations (Stations 564.1, 564.0, and 560.0) to identify potential relationships

between past project construction activities and increased turbidity as well as downstream extent of turbidity impacts (from original construction) in Whitewater River cove. Turbidity data were compiled and presented in a format that shows pre-construction, construction, and post-construction conditions to help inform future potential water quality/turbidity impacts from the construction of Bad Creek II. Additionally, historic water quality data collected by Clemson University on Howard Creek was compiled. Results from these desktop analyses (i.e., Lake Jocassee and Howard Creek) were developed in collaboration with relicensing stakeholders and State resource and regulatory agencies and were provided in the *Existing Water Quality Summary Final Report*⁷, which was submitted with the Initial Study Report as Appendix A, Attachment 1 (Duke Energy 2024).

4.3 Recent Monitoring and Stream Surveys

4.3.1 Lake Jocassee Water Quality Monitoring

Under Task 2 of the Water Resources Study for Project relicensing, locations associated with the three historic water quality stations in Whitewater River cove were monitored to support an analysis of the potential Project-related effects on water resources in the Whitewater River arm (also called the Whitewater River cove) under existing and upgraded unit operations. Specifically, the effectiveness of the existing submerged weir, vertical mixing upstream and downstream of the weir, and the effects of Project discharge on stratification in the Whitewater River cove were evaluated. During study year 1 (2023), objectives were met through continuous and bi-weekly water quality monitoring of water temperature and DO at three historic monitoring stations in the Whitewater River cove of Lake Jocassee. Data collection was carried out from June 1 through September 30 when water temperatures are expected to be warmest and stratification is at its peak. Water quality monitoring efforts are being repeated in the summer of 2024 to capture conditions in the Whitewater River cove with all four existing Bad Creek unit upgrades complete.

In the absence of water quality data or monitoring in Bad Creek Reservoir (upper reservoir), water quality results from this effort provide representative water quality conditions in the upper

⁷ Bad Creek Pumped Storage Project Initial Study Report, FERC eLibrary Accession Number 20240104-5044. URL: https://elibrary.ferc.gov/eLibrary/filelist?accession_num=20240104-5044.

reservoir, as water is exchanged directly between the upper reservoir and the Whitewater River arm of Lake Jocassee.⁸ Additionally, while proposed Project operations are not expected to impose adverse effects on water quality, these baseline water quality data can be used to compare existing conditions to conditions under future construction and operation of Bad Creek II.

4.3.2 Stream Surveys

Disposal of overburden material in upland locations would result in potential impacts to surface waters and will require an individual permit from the USACE and water quality certification from SCDES under the authorities of Sections 404 and 401 of the CWA. In preparation for these expected regulatory processes (if Bad Creek II Complex is pursued), stream habitat quality surveys were completed to provide a physical assessment of existing conditions of streams that have the potential to be impacted.

Under Task 3 (*Impacts to Surface Waters and Associated Aquatic Fauna*) of the Aquatic Resources Study (Duke Energy 2024), stream assessment surveys were conducted as part of the ongoing relicensing for the Project. The goal of this task was to evaluate existing aquatic habitat in waters that have the potential for direct impact from Bad Creek II construction activities by quantifying and characterizing surface waters, including resource quality. In addition to assessing surface waters having the potential to be impacted by construction as described in the Revised Study Plan, Duke Energy evaluated surface waters that would be crossed by the then-proposed temporary access road (Fisher Knob Access Road)⁹. Stream survey approach methods were developed in consultation with the SCDNR and implemented the South Carolina Stream Quantification Tool. Additional details are included in Section 5.2.3.

⁸ Note that water quality monitoring in the Bad Creek Reservoir is not safe (due to rapid, large fluctuations in water level elevation and typically continuous Project operation) nor is it considered meaningful, given the short retention time of the Bad Creek Reservoir. Due to pumping and generating cycles, retention time is approximately three days if only a single pump-turbine unit is operating. There are no existing water quality data in the upper reservoir; it is used only for Project operations and there is no public access.

⁹ The Fisher Knob Access Road was proposed during initial Bad Creek II planning and is therefore included in the scope of this document; however, this alternative route is no longer being pursued by Duke Energy and waters associated with this route will therefore not be evaluated under this Plan.

4.4 SCDES State Water Quality Standards

Under the authority of the South Carolina Pollution Control Act, SCDES Water Classification and Standards¹⁰ establishes appropriate water uses and protection classifications, as well as general rules and specific water quality criteria to protect existing water uses, establish anti-degradation rules, protect public welfare, and maintain and enhance water quality. South Carolina's water quality standards are promulgated in S.C. Regulation 61-68, Water Classifications and Standards. This regulation sets forth the classifications of state waters and establishes water quality standards that protect and maintain the existing and classified uses of those waters. Those beneficial uses, criteria set to protect and maintain those uses, and antidegradation policy are all required components of the water quality standards as set forth in the CWA.

A summary of water quality standards for South Carolina applicable to Project waters (i.e., Blue Ridge; trout waters) is included in Table 3-1. Note that nutrient criteria (i.e., phosphorous, nitrogen, chlorophyll a) in the state of South Carolina apply only to lakes and reservoirs, not rivers and streams. Numeric nutrient criteria are based on an ecoregional approach which considers the geographic location of the lake and are applicable to lakes of 40 acres or more in surface area. In evaluating the effects of nutrients on the quality of lakes and other waters of the state, SCDES may consider, but not be limited to, such factors as the hydrology and morphometry of the waterbody, the existing and projected trophic state, characteristics of the loadings, and other control mechanisms to protect the existing and classified uses of the waters (SCDHEC 2023a).

An important goal of the CWA, South Carolina Pollution Control Act, and the State Water Quality Classifications and Standards is to maintain the quality of surface waters to provide for the survival and propagation of a balanced indigenous aquatic community of fauna and flora (SCDHEC n.d.). The degree to which aquatic life is protected is assessed by comparing important water quality characteristics and the concentrations of potentially toxic pollutants with numeric criteria. Support of aquatic life uses is determined based on the percentage of numeric criteria excursions and, where data are available, the composition and functional integrity of the

¹⁰ Regulation 61-68 Water Classification and Standards: https://scdhec.gov/sites/default/files/Library/Regulations/R.61-68.pdf

FD3

biological community (SCDHEC n.d.). Most named streams in the Project vicinity are classified as trout waters by the SCDES and Lake Jocassee is designated as Trout, Put, Grow, and Take (TPGT) (SCDEHC 2023b)¹¹. TPGT waters are freshwaters suitable for supporting growth of stocked trout populations and a balanced indigenous aquatic community of fauna and flora. These waters are also suitable for contact recreation and as a drinking water supply source after conventional treatment.

Table 3-1. South Carolina Numeric State Water Quality Standards for Parameters
Assessed in Project Waters

Parameter	South Carolina Water Quality Standard	
Temperature (applies to heated effluents only)		
Dissolved Oxygen	Daily average not less than 5.0 milligrams per liter (mg/L) Instantaneous low of 4.0 mg/L Trout Waters: Not less than 6.0 mg/L	
pН	Between 6.0 and 8.5 Trout Waters: between 6.0 and 8.0	
Turbidity	Freshwater Lakes Only: Not to exceed 25 NTU provided existing uses are maintained. Trout Waters: Not to exceed 10 NTU or 10% above natural conditions, provided existing uses are maintained.	
Phosphorus	Blue Ridge – Shall not exceed 0.02 mg/L. Piedmont – Shall not exceed 0.06 mg/L.	
Nitrogen Blue Ridge – Shall not exceed 0.35 mg/L. Piedmont – Shall not exceed 1.5 mg/L.		
Chlorophyll a	Blue Ridge – Shall not exceed 10 μg/L. Piedmont – Shall not exceed 40 μg/L.	

SCDHEC 2023a; mg/L=milligrams per liter; NTU=Nephelometric Turbidity Units; ug/L=micrograms per liter

¹¹Regulation 61-69: Classified waters: https://scdhec.gov/sites/default/files/Library/Regulations/R.61-69.pdf

5 Water Quality Monitoring Plan Development

Potential impacts to water resources are anticipated associated with the construction and operation of the proposed Bad Creek II Complex. Development of the Bad Creek II Complex WQMP is a collaborative effort between Duke Energy, the State regulatory agency (i.e., SCDES), and other relicensing stakeholders and documents methods for monitoring site conditions to maintain project compliance with SCDES ESC requirements in upland watersheds and turbidity water quality standards in the Whitewater River arm of Lake Jocassee.

This Plan is applicable for waters covered under a CWA USACE Section 404 permit/SCDES Section 401 Water Quality Certification and identifies and documents frequency and location of water quality sampling/monitoring for in-water work (Lake Jocassee) as well as locations for qualitative monitoring of upland waters that would be applicable under a SCDES NPDES Construction Stormwater Permit. Potential impacts and monitoring rationale, proposed methods, proposed water quality thresholds, and proposed BMPs are discussed in the following sections to support requirements under both the CWA and SC Pollution Control Act. As indicated in Section 2, the Plan includes temporary and permanent construction activities associated with potential impacts to the lake environment as well as the upland environment and considers separate phases associated with construction. These activities are discussed individually as monitoring methods, environmental setting (streams vs. lake), and types of impact and mitigation for each vary considerably.

Section 5.1 documents potential impacts and monitoring methods in Lake Jocassee, and Section 5.2 considers potential impacts and monitoring methods in upland area surface waters, including those potentially affected by upland spoil disposal sites, site construction activities, and road construction.

Duke Energy will continue to consult with SCDES and other Project stakeholders through the relicensing process and settlement agreement negotiations to determine PM&E measures for the protection of water quality appropriate for construction and operation of the proposed Bad Creek II Complex.

¹² Note that *quantitative* water quality monitoring in upland areas is not required or proposed under this WQMP during the construction phase for the purposes of land disturbance.

5.1 Lake Jocassee

5.1.1 Potential Impacts and Monitoring Rationale

Potential Impacts

- Similar to construction-related impacts for the existing Project, temporarily elevated turbidity levels are anticipated in the Whitewater River arm of Lake Jocassee during construction activities associated with the I/O structure and expansion of the existing submerged weir. Additionally, temporarily elevated turbidity levels in Lake Jocassee due to surface runoff have the potential to occur during high precipitation events impacting construction areas. Therefore, the primary (temporary) impact to surface water quality in Lake Jocassee is increased turbidity caused by potential sediment loading from construction activities (e.g., proposed lower reservoir I/O and cofferdam, bank excavation, expansion of the submerged weir), as well as overland runoff due to temporary land disturbance.
- No long-term degradation of water quality is expected to result from construction and operation of the Bad Creek II Complex.

Monitoring Rationale

• Construction activities could result in temporarily elevated turbidity from sediment loading, which could in turn reduce quality of aquatic habitat. While water quality impacts would be temporary (during construction phase only) and occur in a very localized area likely limited to Whitewater River cove, monitoring water quality at a consistent location in Lake Jocassee during and after construction of the Bad Creek II Complex is proposed to maintain and document compliance with SCDES water quality standards for turbidity. The turbidity water quality standard for trout waters under S.C. Reg.61-69, is not to exceed 10 NTU or 10 percent above natural conditions, provided existing uses are maintained. However, Duke Energy seeks a temporary variance from SCDES during construction of Bad Creek II to meet the turbidity compliance criteria standard for South Carolina freshwater lakes (i.e., 25 NTU). Additional details, including Duke Energy's rationale for seeking a temporary turbidity variance, are included in Section 5.1.3.

5.1.2 Existing Data and Background Information

5.1.2.1 Water Quality in Whitewater River Cove

As indicated above, Duke Energy has monitored water quality conditions in Lake Jocassee in some capacity since its formation (1974). There are 12 historical water quality stations in the lake; two stations (Stations 564.1 and 564.0) are located in Whitewater River cove and one station (Station 560.0) is located downstream of the cove, as shown on Figure 5-1. A summary of surface water quality conditions for the entire lake (from approximately 1976 through 2022) is provided below for a general description of the waterbody. A summary of turbidity results from the previous desktop study for the three stations closest to the Project (Station 564.1, 564.0, 560.0) is also included below to provide information on turbidity trends in the Whitewater River cove before, during, and after original construction.¹³

¹³ Recent modeling results indicate the extent of proposed Bad Creek II project effects is confined to the upstream portion of the Whitewater River cove, therefore, Duke Energy does not propose to monitor historic locations in the reservoir.

Figure 5-1. Duke Energy Water Quality Monitoring Stations Lake Jocassee

Dissolved Oxygen

In general, DO concentrations in Lake Jocassee are a function of the extent of the previous winter mixing – colder winter temperatures result in deeper mixing within the reservoir, which results in higher DO concentrations the following year.

The state standard for DO in trout waters is > 6.0 mg/L (instantaneous minimum). Before 1991 there were two instances of surface DO measuring less than 6.0 mg/L: 4.6 mg/L at monitoring Station 558.0 in 1973 and 5.4 mg/L at monitoring Station 556.0 in 1976, which correspond to the first few years after Lake Jocassee was filled in 1973. There have been no instances of surface DO values less than 6.0 mg/L since Project operations started in 1991.

Over the entire dataset (entire lake), there were 4,241 surface measurements; only five measurements (0.12 percent) were below the state standard (Table 5-1). Surface water DO concentrations in Lake Jocassee fully support the designated use classification (i.e., less than 10 percent criterion excursions).

Table 5-1. Dissolved Oxygen in Surface Waters of Lake Jocassee

Lake Jocassee Surface DO (mg/L)					
Station	Minimum	Average	Maximum		
558.7	6.8	8.7	11.2		
558.0	4.6	8.7	11.2		
559.0	6.9	8.7	11.1		
560.0*	6.1	8.7	11.8		
562.0	6.9	8.8	11.3		
565.4	7.4	8.8	11.2		
551.0	7.2	9.9	14.4		
564.0*	6.6	8.8	12.2		
564.1*	6.6	8.6	11.1		
557.0	6.7	8.9	11.6		
554.8	6.7	8.9	11.2		
556.0	5.4	9.0	11.6		

^{*} Whitewater River cove monitoring station

Bad Creek operational impacts to DO are limited to monitoring Station 564.1 between the I/O structure and submerged weir. Monthly average DO concentrations within the water column at this location are nearly uniform after 1991 (post Bad Creek operation). Vertical mixing from Bad Creek operations does not allow for stratification at this monitoring location regardless of season. DO stratification does occur at monitoring Station 564.0 (downstream of the weir), and there is

very little difference in DO profiles between pre and post Bad Creek operation indicating the submerged weir is functioning as intended.

Temperature

Water temperature dictates the types of biota that can survive in a waterbody, affects metabolic rates and photosynthesis, influences the rates of chemical reactions, and impacts the physical capacity of water to hold DO. Historical surface water temperature minimum, average, and maximum values for all stations are included in Table 5-2. Discrete water quality data assessed in Lake Jocassee consistently met South Carolina water quality standards for trout waters for temperature. There is no numeric threshold for temperature, however, for trout waters, narrative criteria indicate water temperatures should not vary from levels existing under natural conditions (unless determined some other temperature shall protect the classified uses), which is supported by study findings.

Table 5-2. Water Temperature in Surface Waters of Lake Jocassee

Lake Jocassee Surface Temperature (degrees C)					
Station	Minimum	Average	Maximum		
558.7	8.20	18.59	29.02		
558.0	7.10	18.44	28.22		
559.0	8.10	18.81	28.90		
560.0*	7.10	18.87	28.47		
562.0	8.10	19.23	29.20		
565.4	8.50	18.84	28.50		
551.0	0.20	13.48	27.24		
564.0*	7.40	19.15	28.61		
564.1*	8.50	18.99	28.40		
557.0	7.10	18.81	29.23		
554.8	7.70	19.24	29.15		
556.0	7.30	19.04	29.12		

^{*} Whitewater River cove monitoring station

Similar to DO vertical profile trends, Bad Creek operational impacts to temperature are limited to monitoring Station 564.1 upstream of the weir. Vertical mixing from Bad Creek operations does not allow for stratification at this monitoring location regardless of season. DO stratification does occur at monitoring Station 564.0 (downstream of the weir), and there is very little difference in temperature profiles between pre and post Bad Creek operation indicating the submerged weir is functioning as intended.

pH

Surface pH values for all stations are included in Table 5-3. Instantaneous pH surface readings were compared against the pH state standard for trout waters (6.0-8.0 Standard Units). Over the entire dataset, there were 4,253 samples assessed; two samples were above the state standard (i.e., less than 1 percent of the dataset) and 255 samples were below the state standard (i.e., 6 percent of the dataset). Therefore, surface water pH levels in Lake Jocassee fully support the designated use classification (i.e., within 10 percent criterion excursions).

Surface Phosphorous (Standard Units) Station Minimum Average Maximum 558.7 5.50 6.67 7.60 558.0 5.20 8.00 6.56 7.71 559.0 5.30 6.67 560.0* 5.60 6.69 7.80 7.90 562.0 5.60 6.76 565.4 5.60 6.50 8.10 551.0 5.50 6.53 7.90 564.0* 7.90 5.60 6.78 564.1* 7.90 5.60 6.73 557.0 5.50 6.73 7.80 8.10 554.8 5.60 6.84 556.0 5.63 6.80 7.90

Table 5-3. pH in Surface Waters of Lake Jocassee

Turbidity

Turbidity is a measure of the amount of suspended particles in water (determined by the amount of light scattered); because turbidity is simply the amount of light that can pass through water, turbidity values can increase due to any solid particles in the water, including organic material and microscopic organisms. While turbidity is not an inherent property of water like temperature and DO, it is recognized as an indicator of environmental health of a waterbody (USGS 2018). Turbidity levels in a waterbody are typically episodic in nature and are not spatially or temporally consistent. Under natural conditions, suspended sediment load contribution to a receiving waterbody increases during a rainstorm/runoff event where sediment is eroded from upland areas or stream banks and flows into surface waters. Another major contributor to upland soil/sediment erosion is construction activities; these activities are often short-lived but can result in large amounts of soil released from the land that is subsequently transported to adjacent waterbodies. Depending on the magnitude of the rain event, amount and grainsize of sediment,

^{*} Whitewater River cove monitoring station

proximity to the point of entry, and character of a waterbody, sediment can settle out quickly after the event or may remain suspended in the water column for some time after the event.

During original Project construction, turbidity levels in the Whitewater River cove of Lake Jocassee were impacted by construction activities. During recent relicensing study efforts, a desktop study was carried out to evaluate historical turbidity data in the Whitewater River cove at the three monitoring stations closest downstream of the Project and determine if original construction activities resulted in a noticeable increase in turbidity values and if so, estimate how far downstream impacts extended and for how long turbidity was elevated. This was done by comparing turbidity values from pre-construction (<1985), construction (1985-1991)¹⁴, and post-construction (1992-2015). Note that, unlike temperature and DO, turbidity does not show spatial trends or stratification patterns; turbidity measurements represent a snapshot in time and are typically driven by external factors.

Surface turbidity values were assessed over the entire dataset (1976-2015) for stations 560.0, 564.0, and 564.1 (Table 5-4). A boxplot of surface turbidity data over all time periods is also provided in Figure 5-2 to show the distribution of surface turbidity at these stations. Over the entire dataset, there were 550 surface samples assessed; 9 samples were above the state standard (i.e., 10 NTU), which accounts for 0.02 percent of the dataset (this also includes data collected during construction). Surface water turbidity levels in Lake Jocassee fully supported the designated use classification (i.e., less than 10 percent criterion excursions).

Table 5-4. Turbidity in Surface Waters of Whitewater River Cove

Turbidity (NTU)						
Station	Minimum	Average	Maximum			
560.0	0.00	1.90	17.00			
564.0	0.00	1.96	47.00			
564.1	0.00	1.61	19.00			

¹⁴ Duke Energy is proposing to expand the existing submerged weir with newly excavated rockfill from the proposed Bad Creek II Complex in part to help mitigate the impacts of a second I/O structure in Whitewater River cove. Assessing pre-construction turbidity data and estimating impacts to turbidity during original construction may help inform water quality conditions during proposed construction of the Bad Creek II Complex.

Figure 5-2. Surface Turbidity in the Whitewater River Arm during Pre-Construction, Construction, and Post-Construction Periods

5.1.2.2 Lake Jocassee Reservoir Level Fluctuation Effects on Water Quality

Additional pumping and generating capacity of the Bad Creek II Complex would reduce the time for maximum drawdown and refill of the upper reservoir; however, it would not result in additional water level rise in Lake Jocassee. Modeling carried out through relicensing efforts¹⁵ showed that scenarios under Bad Creek II resulted in a decreased reservoir fluctuation band indicating more consistent water levels than under current conditions. These changes in water level fluctuation are not expected to affect water quality in Lake Jocassee.

¹⁵ Details from the modeling effort are included in the *Water Exchange Rates and Lake Jocassee Reservoir Levels Final Report* and the *Effects of Bad Creek II complex and Expanded Weir on Aquatic Habitat Final Report* developed in coordination with relicensing stakeholders and submitted with the Updated Study Report.

5.1.3 Proposed Methods

5.1.3.1 Proposed Water Quality Parameters and Temporary Turbidity Variance

Water quality monitoring in the Whitewater River cove of Lake Jocassee will follow established Duke Energy procedures and standard methodology. Duke Energy proposes to monitor the following water quality parameters during the construction and post-construction phases:

- Turbidity
- DO
- Temperature
- pH

Data will be compared to State water quality criteria (Table 3-1). During the construction phase, all four parameters will be measured, but only turbidity data will be used to inform construction activities, since increased suspended loading is the proposed impact. The turbidity water quality standard for trout waters (e.g., TPGT) under S.C. Reg.61-69 is *not to exceed 10 NTU or 10 percent above natural conditions*, provided existing uses are maintained. However, Duke Energy seeks a temporary variance from SCDES at the proposed point of compliance (see Section 5.1.3.4 for proposed monitoring location) during construction of Bad Creek II to meet the turbidity compliance standard for South Carolina freshwater lakes (i.e., 25 NTU). According to S.C. Reg.61-69, a temporary variance is "a short-term exemption from meeting certain otherwise applicable water quality standards" and may be granted by the SCDES provided the following apply:

- a. The variance is granted to an individual discharger for a specific pollutant(s) or parameter(s) and does not otherwise modify water quality standards; and
- b. The variance identifies and justifies the criterion that shall apply during the existence of the variance; and
- c. The variance is established as close to the underlying criterion as is possible and, upon expiration of the variance, the underlying criterion shall become the effective water quality standard for the waterbody; and
- d. The variance is reviewed every three (3) years, at a minimum, and extended only where the conditions for granting the variance still apply; and
- e. The variance does not exempt the discharger from compliance with any applicable technology or other water quality-based permit effluent limitations; and
- f. The variance does not affect permit effluent limitations for other dischargers.

Duke Energy understands that prior to removing any uses or granting a variance, notice and an opportunity for a public hearing shall be provided by SCDES.

As mentioned above, a turbidity threshold of 25 NTU is considered protective of water and aquatic resources in freshwater lakes in South Carolina; however, since Lake Jocassee is considered TPGT waters, the state criteria is 10 NTU. In general, elevated suspended sediment can have behavioral, physical, and habitat effects on fish in a waterbody. Fish response to suspended sediment is dependent on many environmental factors such as (Bash and Berman 2001; Servizi and Martens 1992):

- duration and frequency of exposure
- water temperature
- fish life stage
- particle characteristic (e.g., angularity, size, toxicity, type)
- magnitude of turbidity pulse
- timing of turbidity pulse (e.g., season)
- natural background turbidity and
- availability of refugia.

Research has found that duration of suspended sediment exposure plays a more dominant role than suspended sediment concentration (Anderson et al. 1996). Non-salmonid species (e.g. bluegill) are considered tolerant of turbidity levels of up to approximately 50 NTU (Gardner 1981). Lloyd (1987) indicated that for salmonids, which are more sensitive to water quality conditions, a "moderate" level of protection (suspended solids concentration up to 100 mg/l) roughly translates to turbidity values up to 23 NTU. Avoidance is the primary fish behavioral response to locally turbid water; species more sensitive to sediment loads may be forced to move to other areas of the system to avoid negative effects on survival driven by direct effects of water quality conditions, or indirect effects such as decreased visual detection of predators and prey. Fish may seek out "turbidity refugia" when subjected to short-term pulses of sediment, and salmonids will move laterally (Servizi and Martens 1992) or downstream to avoid turbid areas (McLeay et al. 1987). In laboratory experiments, it has also been shown that salmonids will move to less turbid waters, if available, after a short-term pulse (of sediment) (Berg and Northcote 1985). Bisson and Bilby (1982) illustrated the displacement of some salmonids in water with turbidities greater than 70 NTU, while Sigler et al. (1984) and Lloyd (1987) noted avoidance of turbid water may begin as turbidity approaches 30 NTU. Regardless of the type or

magnitude of the impact, it is important that areas of refugia are available and accessible for more sensitive populations. While the Whitewater River cove could potentially be affected by pulses of increased suspended sediment during certain construction activities (e.g., cofferdam removal, weir construction); this area accounts for just 1.5 percent of the total area of Lake Jocassee, therefore a large turbidity refugia (98.5 percent of the lake) would be available to sensitive species.

During original construction activities, historical data indicate consistently low turbidity levels in surface waters downstream of the Project during construction, however, historic turbidity measurements were collected prior to project operations. Duke Energy anticipates higher turbidity levels with the construction of Bad Creek II (compared to original construction) because the existing Project will be operating, thereby moving water upstream and downstream through the Whitewater River cove during pumping and generation cycles, respectively. It is not presently known what sort of impact construction or operations will have on turbidity levels at the water surface. Therefore, because (1) sensitive populations will be able to avoid areas of higher turbidity and move into other areas of Lake Jocassee (i.e., abundant availability and accessibility to turbidity refugia exists) and (2) potentially increased turbidity levels will be temporary (i.e., fish that do move out of the Whitewater River cove to avoid higher turbidities are expected to return following the impact), a more conservative turbidity threshold of 25 NTU for compliance reporting, which would still be protective of natural resources, would allow Duke Energy to construct the new facility while maintaining compliance with state regulations, which is a critical focus of Duke Energy for any project.

5.1.3.2 Data Collection and Evaluation

SCDES guidance states that grab samples or samples collected at a depth of 0.3 meters are considered for the purpose of water quality assessment, and only surface samples should be used in standards comparisons and trend assessments (SCDHEC n.d.). The SCDES and U.S. Environmental Protection Agency (USEPA) do not define the sampling method or frequency of sampling for water quality to compare to criteria, other than indicating it should be "representative" (SCDHEC n.d.).

To ensure compliance with SCDES water quality requirements for turbidity, Duke Energy will measure surface water conditions approximately 0.3 meters below the surface. A new monitoring station (see Section 5.1.3.4) will be instrumented with a multi-parameter water quality sonde and high-visibility buoy at the downstream end of Whitewater River cove near the proposed boat barrier. The data sonde will record water quality parameters daily (i.e., turbidity, DO, temperature, and pH) and store readings on an internal memory drive; data collection may require minor modification depending on field conditions. Data will be transmitted and received electronically (by Duke Energy personnel) via telemetry or by manual download in the field if telemetry is not available.

Data will be reviewed routinely (weekly) during construction and bi-weekly to monthly post-construction. If telemetry options are not available for data transmission, data will be manually downloaded in the field weekly during active construction period and bi-weekly to monthly during the post-construction monitoring period. Duke Energy-owned equipment will be used to collect the water quality data, and either Duke Energy or a consultant to Duke Energy will be responsible for retrieving and analyzing the data.

5.1.3.3 Excursions

The purpose of the State Water Quality Classification and Standards (SCDHEC 2023a) is to maintain the quality of surface waters to provide for the survival and propagation of a balanced indigenous aquatic community of fauna and flora and the degree to which aquatic life is protected (Aquatic Life Use Support) is assessed by comparing important water quality parameters with numeric criteria (SCDHEC n.d.). Support of aquatic life uses is determined based on the percentage of numeric criteria excursions. The term excursion is used to describe a measured pollutant concentration that is outside of the acceptable range as defined by the appropriate criterion (see Table 3-1). Per SCDHES standards for turbidity in surface waters (SCDHEC n.d.), if criteria are exceeded in more than 25 percent of the samples over 30 days, the criterion is not supported and it constitutes a violation of water quality. If the criterion is exceeded in more than 10 but less than 25 percent of the samples, sites are evaluated on a case-by-case basis to determine if local conditions indicate that classified uses are impaired. If the criterion is exceeded in less than 10 percent of the samples, then the criterion is fully supported. Some waters may exhibit characteristics outside the appropriate criteria due to natural

conditions. Such natural conditions do not constitute a violation of the water quality criteria. Duke Energy proposes to adapt this sampling strategy for the Bad Creek II WQMP for monitoring in Lake Jocassee, as described below.

As indicated in Section 5.1.3.1, turbidity will be used to inform construction activities. The criteria for identifying an excursion and actions to be taken if turbidity readings exceed the compliance threshold are as follows:

- An excursion is defined as any surface reading above the State water quality standard for turbidity (compliance threshold) (e.g., 25 NTU).
- If daily readings exceed the turbidity compliance threshold more than 10 percent (but less than 25 percent) of readings over a rolling 30-day period, Duke Energy will investigate to determine if excursions are the direct result of construction activities (e.g., lower I/O and cofferdam construction, weir expansion) or rain events.¹⁶
- If elevated turbidity is determined to be the result of a rainfall event (i.e., overland flow and runoff), data characterizing the rain event (timing and amount of precipitation) will be documented using the nearest weather station along with corresponding turbidity data.
- If turbidity excursions are not clearly linked to a rainfall event (i.e., attributable to construction-related activities), Duke Energy will consult with SCDES if daily readings exceed the turbidity compliance threshold of more than 10 percent but less than 25 percent of readings over a rolling 30-day period. Similarly, Duke Energy will consult with SCDES if daily readings exceed 25 percent of readings over a 30-day period.

5.1.3.4 Proposed Monitoring Location

Duke Energy proposes to install a new water quality monitoring station located near the confluence of Whitewater River arm with the main portion of the lake (Station 563.0; see Figure 5-3). A proposed positive boat barrier will be deployed across the width of the Whitewater River cove at the confluence during the construction phase to prevent recreational boating in Whitewater River cove, therefore, the proposed point of compliance for water quality monitoring

¹⁶ Historical data shows turbidity in Whitewater River Cove naturally increases during large storm events due to run off from tributaries and overland flow. For example, on August 16, 1994, rainfall associated with Tropical Storm Beryl resulted in consistently high turbidity readings for several days.

FD3

will be near the boat barrier to safely facilitate boat access to the water quality station for maintenance and data downloading. A photo-rendering of the temporary boat barrier extending across Whitewater River cove is shown on Figure 5-4.

Figure 5-3. Proposed Compliance Point (Station 563.0) and Proposed Temporary Boat Barrier

The proposed location is near Station 564.0, which has many years of turbidity data associated with it from before, during, and after original Project construction, and is also near locations assessed during the 2023 and 2024 water quality relicensing study.

The proposed monitoring station is approximately 4,225 ft (0.8 mile) downstream from the proposed I/O structure and 2,370 ft (0.45 mile) downstream of the upstream end of the submerged weir. Duke Energy believes this location would be close enough to adequately monitor potential water quality impacts associated with Bad Creek II major construction activities (i.e., cofferdam construction, I/O structure and bank disturbance, submerged weir expansion) in Lake Jocassee.

Figure 5-4. Rendering of Proposed Boat Barrier downstream of the Lower Reservoir I/O for Water Quality Compliance Monitoring

5.1.3.5 Proposed Sampling Frequency

While the Revised Study Plan suggested a general pre-construction monitoring task, it was determined during Plan development that for water quality monitoring in the Whitewater River cove, SCDES surface water quality standards are more relevant for evaluating water quality criteria thresholds than comparing against existing water quality data, therefore, pre-construction monitoring was deemed unnecessary in Lake Jocassee (i.e., the objective is to remain in compliance with state water quality standards, not to ensure recovery to an existing condition). SCDES water quality criteria are designed to be protective of aquatic habitat, therefore compliance with water quality standards is anticipated to be protective of aquatic life in the lake. Construction and post-construction monitoring will also benefit the extensive historical water quality data collection in Lake Jocassee.

Pre-construction

Pre-construction monitoring will not be performed as documentation of recovery to an existing condition and is not an objective of this WQMP.¹⁷

Construction

Water quality parameters will be recorded daily for the duration of Bad Creek II construction phase via a multi-parameter sonde deployed at the proposed point of compliance (see Section 5.1.3.4). Data will be reviewed weekly.

Post-construction

Water quality parameters will be recorded daily for one year (365 days) following commencement of Bad Creek II commercial operation via a multi-parameter sonde deployed at the proposed point of compliance (see Section 5.1.3.4). Data will be reviewed bi-weekly to monthly.

¹⁷ As described above, Duke Energy has historical and current water quality data for the Whitewater River cove; a summary of existing data is included in the ISR (Duke Energy 2024).

5.1.4 Proposed Reporting Criteria

Water quality data will be reported per requirements of the SCDES 401 Water Quality Permit and appropriate agencies would be consulted. An annual report will be developed by April 15 each year for filing with SCDES with a courtesy copy to FERC.

5.1.5 Summary

Temporary, short-term effects (associated with elevated turbidity) are possible in the Whitewater River cove associated with construction activities on land, overland runoff, and the expansion of the submerged weir. BMPs will be implemented (on land) to reduce sedimentation into waters of the U.S. (WOTUS).

No long-term effects on the population, abundance, or distribution of forage fish in Lake Jocassee are anticipated as a result of the proposed Bad Creek II Complex construction or operations. Similarly, no long-term effects on the littoral fish populations or changes in suitable habitat are anticipated as a result of the proposed Bad Creek II Complex operations (see Section 5.1.2.2). As indicated in Section 4.1, certain water quality activities will continue in Lake Jocassee throughout the KT license term including the agreement to maintain pelagic trout habitat in Lake Jocassee and continuance of water quality monitoring in the tailrace.

Duke Energy's proposed monitoring strategy addresses potential challenges in meeting SCDES water quality standards during construction by reviewing turbidity data routinely (weekly) during construction immediately downstream of the Project so that any turbidity-related issues can be identified quickly and mitigative management controls applied if necessary. Because there is abundant availability and accessibility to turbidity refugia and potentially increased turbidity levels will be temporary, Duke Energy is seeking a temporary water quality turbidity variance of 25 NTU at the Whitewater River cove compliance point downstream of Bad Creek II for the duration of construction activities.

5.2 Upland Areas Surface Waters

5.2.1 Potential Impacts and Monitoring Rationale

Potential Impacts

- Construction of the Bad Creek II Complex would impact existing upland surface waters. Overburden (i.e., soil and rock) material from the construction activities are proposed to be deposited in several spoil locations throughout the site; locations are currently under evaluation. Construction activities could potentially lead to temporary impacts to water quality due to increased turbidity from sediment loading. Due to the estimated amount of spoil material, existing topography, and prevalence of headwater streams and seeps located throughout the site, it is unlikely there would be a practicable alternative identified that will result in zero impacts to steams and downstream waters.
- Estimates for proposed material removed from underground excavations indicate approximately 4.4 million cubic yards of spoil material for the Project infrastructure will need to be deposited into on-site spoil locations or along the submerged weir in Lake Jocassee. Placement of excavated rock removed from the underground excavations to the downstream slope of the existing submerged weir in Lake Jocassee, as was done for the construction of the existing Project, would significantly reduce the amount of material to be placed at upland disposal sites, thereby reducing potential impacts to upland waters.
- Traffic on access roads during construction has the potential to increase sediment runoff which can be mitigated through BMPs (e.g., vegetation, silt fence, or matting) installed near haul roads and access roads. BMP inspections and the ESC Plan will be developed and implemented through the NPDES construction permitting process and, therefore, potential impacts, mitigation, and monitoring associated with construction-related access roads are not addressed in the WQMP.

Monitoring Rationale

Increased sediment loading during rainfall runoff events could impact existing streams
and waterbodies during construction activities. While no long-term degradation of water
quality is expected to result from construction of the Bad Creek II Complex, activities

could potentially lead to temporary impacts to water quality due to increased turbidity, therefore Duke Energy proposes to install and maintain BMPs in accordance with SCDES permit requirements to mitigate risks to streams impacted by spoil placement associated with Bad Creek II construction activities.

- Upland placement of spoil materials will result in potential impacts to surface waters. Therefore, an individual permit from the USACE will be required as well as a water quality certification from SCDES under the authorities of Sections 404 and 401 of the CWA 18. Note that the upland disposal areas (e.g., spoil areas) will also be located within the overall Project Limits of Disturbance (LOD) and the construction phase activities and temporary land disturbance impacts will be covered under the SCDES NPDES Construction General permit (e.g. erosion and sediment control permit). The LOD will be planned with perimeter and internal BMPs such that the overland stormwater flow / water quantity will be managed. Water quality monitoring is not required or proposed as part of the SCDES Construction General NPDES permit.
- During construction, temporary BMPs (e.g., sediment basins, silt fences, waddles, etc.)
 proposed under the SCDES Construction General Permit will be installed, regularly inspected, and maintained to control runoff from affected areas into surface waters.
- While no long-term degradation of water quality is expected to result from construction of the Bad Creek II Complex, these activities could result in temporary impacts, therefore, Duke Energy proposes to conduct stream habitat quality assessment surveys in perennial streams associated with drainage from spoil areas. These would consist of (year-round) accessible downstream reaches where the cumulative effect of construction activities can be observed. These locations would be used to document stream conditions and function where water has flowed from the construction area, through a BMP, and into WOTUS. Pre-construction monitoring in these areas will be compared with similar post-construction monitoring to document construction-related impacts and also determine when these areas have recovered to pre-construction conditions and to help plan for site restoration / stabilization.

¹⁸ This process has been initiated in parallel with the relicensing process.

5.2.2 Existing Data and Background Information

During 2021, 2022, and 2023 efforts for the relicensing and advancement of the proposed project, on-site streams were assessed in coordination with the SCDNR and other relicensing stakeholders. In addition, WOTUS surveys were carried out in summer 2024 in support of identifying waters of the U.S. and USACE permitting.

5.2.2.1 Stream Habitat Quality and Macroinvertebrate Surveys

As stated above, the disposal of overburden material in upland locations would result in impacts to surface waters and will require authorization under an individual permit from the USACE and water quality certification from SCDES under the authorities of Sections 404 and 401 of the CWA. In preparation for these expected regulatory processes, stream habitat quality surveys were completed to provide a physical assessment of the existing conditions of streams that have the potential to be impacted.

In accordance with the FERC-approved Aquatic Resources Revised Study Plan, the stream habitat assessment portion of the USEPA Rapid Bioassessment Protocol was completed for streams within potential spoil locations. Streams and creeks crossed by the then-proposed temporary access road were also assessed. The North Carolina Stream Assessment Method (NCSAM) ¹⁹ was completed for streams within potential spoil locations and streams or creeks crossed by the temporary access road. The SC Stream Quantification Tool (SQT) was developed in a collaborative effort between federal and state representatives to provide a tool for assessing and quantifying functional lift and loss of streams in South Carolina. In May 2023, the SCDNR requested that Duke Energy apply the SQT methods to streams within potential spoil locations and streams crossed by the then-proposed temporary access road. Duke Energy consulted with the SCDNR in May and June 2023 regarding the applicability and methodology of the SQT for stream assessments. In July 2023, Duke Energy and the SCDNR conducted a site visit to two potential spoil locations representative of conditions across the site. It was agreed among the

¹⁹ While the Project is located in South Carolina, the site is close to the border of North Carolina and many of the streams in the Project vicinity have headwaters in North Carolina. Implementation of the NCSAM is appropriate for assessing Project waters as this method is based on valley shape, watershed size, and physiographic region; these characteristics are consistent between streams in the mountainous area surround the Project, regardless of the state.

SCDNR staff and Duke Energy personnel that streams within potential spoil locations are generally high functioning with limited (if any) anthropogenically caused degradation, and that field data collection to support SQT analysis for other similar streams in these areas were not likely to produce significantly different results (i.e., lower functionality scores) than an assumption of fully functional. Therefore, Duke Energy proposed to conduct field surveys on streams potentially crossed by the then-proposed temporary access road, only. Documentation of all consultation for the Aquatic Resources study is included in Attachment 4 of Appendix B of the Initial Study Report.

In addition, macroinvertebrate surveys of Limber Pole Creek and Howard Creek found abundant Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies) (also referred to as EPT) taxa and habitat conditions, also resulted in a high bioclassification score indicating a fully supporting system.²⁰

Detailed results from the stream assessments are included in the *Impacts to Surface Waters and Associated Aquatic Fauna* final report, which was developed in collaboration with relicensing stakeholders and State resource and regulatory agencies and submitted with the Initial Study Report as Appendix A, Attachment 1 (Duke Energy 2024).

5.2.2.2 WOTUS Surveys

HDR as a consultant to Duke Energy, delineated potential WOTUS according to the USEPA and USACE operative definition of Pre-2015 Regulatory Regime consistent with Sackett vs. Environmental Protection Agency to provide an opinion on the jurisdictional status of the identified features (effective on August 29, 2023). Field efforts were planned and informed based on previous field reconnaissance and natural resource assessments, as well as review of existing publicly available information, including data from U.S. Geological Survey (USGS) 1:24,000 topographic quadrangles, the USGS National Hydrography Dataset, and USFWS National Wetland Inventory, as well as Natural Resources Conservation Service soil maps. HDR conducted on-site delineations of jurisdictional WOTUS, including wetlands and waterbodies.

²⁰ During electrofishing fish sampling activities, water quality parameters included temperature, DO, specific conductivity, pH, salinity, and turbidity and were collected in July, September, and October on Limber Pole Creek and Howard Creek.

Natural resources assessments to identify surface waters and wetlands within potential spoil locations were completed in September 2021 and September 2023 along the then-proposed temporary access road. The 2023 results indicated the proposed access road would potentially cross Howard Creek and Limber Pole Creek and several of their tributaries. Overall, WOTUS surveys were carried out within the proposed Project Boundary on June 8 to 10, 2021; September 19 and 20, 2021; October 18 and 19, 2023; May 21 to 23, 2024; July 23 to 25, 2024; July 31, 2024; August 1, 2024; and August 16, 2024. The combined waters delineations revealed the potential for over 120 streams, 43 wetlands, and several open waters located within the proposed expanded FERC Project Boundary.

HDR, on behalf of Duke Energy, submitted a Preliminary/Approved Jurisdictional Determination Request to the USACE for waters of the U.S. within the Project Boundary on September 9, 2024. On December 3, 2024, HDR met with the USACE Charleston Regulatory Office for a site visit at the Project to field-verify the on-site waters and wetlands. Field results identified 51 jurisdictional streams and 8 jurisdictional wetlands, respectively, in the main Project site, along with 40 jurisdictional streams and 17 jurisdictional wetlands in the transmission line corridor. Jurisdictional waters and wetlands for the main Project site area (i.e., excluding transmission line corridor) and their locations relative to potential spoil areas are shown on Figure 5-5.

5.2.3 Proposed Methods

5.2.3.1 Data Collection and Processing Methods

BMP Monitoring and Inspections

During construction, temporary BMPs (e.g., sediment basins, silt fences, waddles, etc.) proposed under the SCDES Construction General Permit will be installed and maintained to control runoff from affected areas into surface waters. These BMPs will be sized according to elevated standards (i.e., sediment basins and rock dams shall be designed to treat the peak runoff from at least the 25-year²¹ storm and may have larger dimensions than typical devices for standard

²¹ Per Duke Energy's Construction Stormwater Planning Manual for Operations in Environmentally Sensitive Areas (Duke Energy 2019). Environmentally Sensitive Areas are surface waters and their surrounding riparian areas that require special protection during construction due to the sensitive nature of the resource.

areas), including an added layer of 18-inch compost socks on the low side of sites draining to wetlands or streams. BMPs will be located within site drainage areas and intermediate BMPs placed within areas of expected flow and retention to attenuate water quantity. An additional 50-foot undisturbed buffer beyond the regulatory-required buffers for wetland and stream will be implemented. Land disturbance will be restricted within the proposed LODs to include the proposed construction features, construction access, and materials staging / laydown, as well as the locations of BMPs to manage construction runoff from these areas. Based on required compliance monitoring under the SCDES Construction General Permit, weekly and post-storm (e.g., rainfall greater than 1 inch within a 24-hour period) inspections of the LOD will be conducted. These inspections are based on functionality of the BMPs and maintenance actions are commonly identified for future tracking and/or verification of completion. A copy of the SCDES Construction General Permit and the Onsite-Stormwater Pollution Protection Plan (OS-SWPPP) will be kept onsite in accordance with permit requirements.

If additional BMPs or adjustment of BMPs are required based on onsite observations and inspections, the OS-SWPPP will be red-lined for tracking.²² Determining the location of BMPs and proposed LODs is not an objective of this WQMP.

Stream Habitat Quality Surveys

Several stream assessment methods will be implemented to carry out stream habitat quality surveys to provide information on conditions of streams that have the potential to be impacted by construction activities and spoils placement. These methods are in alignment with methods carried out for previous studies performed for the relicensing (as described above) and include the following:

- USEPA Rapid Bioassessment Protocol (Barbour et al. 1999)
- NCSAM (N.C. Stream Functional Assessment Team 2013)

²² SCDES's Construction Permit, also referred to as the Erosion and Sediment Control / Construction Stormwater Permit, requires submittal of a Notice of Intent for permit coverage for clearing, grading, or excavating activities disturbing >1 acre. Permit application must include a Comprehensive Stormwater Pollution Prevention Plan (C-SWPPP) and an Onsite (OS)-SWPPP during the construction phase. Emissions and dust control measures must also conform to regulatory requirements (Fugitive Dust Control [61-62.6]) and can be incorporated into the Erosion and Sediment Control permit. (See SC Code Sections 48-14-10 et seq., SC Regulation 72-300 – 72-316 for additional information.)

- SQT (South Carolina Steering Committee 2022)
- Macroinvertebrate sampling (SCDHEC 2017)

5.2.3.2 Proposed Monitoring Location(s)

Upland Spoil Areas

• For perennial streams associated with drainage from spoil areas, the point of compliance will be in an accessible downstream reach where the cumulative effect of the construction can be observed. This location will be used to document stream conditions and function where water has flowed from the construction area, through a BMP, and into a WOTUS. Proposed monitoring locations are shown on Figure 5-5. (Note that some areas preclude monitoring stations due to steep terrain, e.g., downstream of Spoil Area C).

Access Roads

Streams associated with access roads will not be monitored as part of this Plan; these
roads, along with transmission line access areas, will have standard Duke Energy BMP
measures installed. BMP inspections and the ESC Plan will be developed and
implemented through the NPDES construction permitting process and, therefore,
potential impacts, mitigation, and monitoring associated with construction-related access
roads are not addressed in the WQMP.

Figure 5-5. Proposed Stream Habitat Quality Monitoring Locations and Preliminary Spoil Areas

5.2.3.3 Sampling Frequency

Pre-construction

Pre-construction stream habitat quality surveys of upland surface waters that will be impacted by spoils placement and site construction activities will be conducted to document existing conditions and function. Pre-construction surveys will be carried out prior to installation of BMPs.

Construction

Construction phase stream assessment surveys will not be carried out in areas that are protected by BMPs required by SCDES environmental permits. Duke Energy will regularly inspect and maintain BMPs to help minimize downstream potential impacts to surface waters. Based on required compliance monitoring under the SCDES Construction General Permit, weekly and post-storm (e.g., rainfall greater than 1 inch within a 24-hour period) inspections of the LOD will be conducted.

Post-construction

Post-construction stream quality habitat surveys of upland surface waters impacted by spoils placement and site construction activities will be performed to document post-construction conditions and function. Duke Energy proposes surveys at 1-year, 3-years, and 5-years following commencement of Bad Creek II operations. If necessary, an additional survey will be carried out at 7 years post-construction to ensure streams provide fully functioning and supportive habitat and replicate original (existing) stream conditions.

5.2.4 Reporting

Inspections and maintenance of BMPs during construction will be carried out per NPDES construction permit requirements. Weekly and post-storm inspections inform whether maintenance and/or replacement of BMPs, such as silt fence, rock outlets, compost filter socks, or areas of stone, need to be conducted. Based on the condition of the BMP and level of work required to keep functionality, the inspector will work with Duke Energy's environmental oversight team to identify the timing of the work. In an instance of a BMP failure, typically, the

BMP is repaired or replaced, and timing is based on proximity to environmental sensitive areas as well as availability of materials.

For post-construction stream habitat quality surveys, areas that have not recovered to preconstruction conditions and function within one year of commercial operation will be evaluated for additional monitoring in consultation with SCDES. Appropriate agencies would also be notified and consulted to determine the next steps. Water quality reporting for the Whitewater River cove will be carried out in accordance with applicable permitting requirements.

A comprehensive ESC Plan and C-SWPPP will be developed and implemented for all construction phases of the Bad Creek II Complex. BMPs will be sized and sited to manage overland stormwater flow within the LOD as part of the ESC Plan. Additionally, under the NPDES permitting process, a prevention, control, and safety management plan to prevent vehicle spilled fluids from entering the watersheds and harming water quality will be developed and implemented.

6 Stakeholder and Agency Coordination

A meeting between Duke Energy, SCDES, and Duke Energy's consultant (HDR) was held on August 8, 2024, to discuss objectives and methods outlined in the WQMP as well as permitting requirements for the CWA 401 Water Quality Certification; the draft WQMP was submitted to SCDES for review on August 28, 2024, and comments were received on September 23, 2024. Agency comments were addressed in a revised draft and on October 4, 2024, Duke Energy distributed the draft WQMP to the Aquatic and Water Resources Committees for a 30-day review period. No additional comments were received. This final WQMP will be filed with the Water Resources Study Report in the Final License Application along with stakeholder consultation documentation.

Attachment 6 **Consultation Documentation**

Meeting Summary

Project: Bad Creek Pumped Storage Project Relicensing

Subject: Bad Creek Water Resources Committee Meeting

Date: Tuesday, May 16, 2023

Location: Teams (Virtual)

Attendees

John Crutchfield, Duke Energy Maverick Raber, Duke Energy Alan Stuart, Duke Energy Joe Dvorak, HDR Sarah Kulpa, HDR Kerry McCarney-Castle, HDR Ty Ziegler, HDR Lynn Quattro, SCDNR Dan Rankin, SCDNR Amy Chastain, SCDNR Elizabeth Miller, SCDNR Alex Pellett, SCDNR Dale Wilde, Friends of Lake Keowee Society Erika Hollis, Upstate Forever Jeff Phillips, Greenville Water

Introduction

John Crutchfield opened the Water Resources Committee meeting and facilitated introductions. John noted the virtual meeting was being recorded for those Committee members not present or other interested individuals in viewing the presentation and to aid in meeting minutes preparation. He then handed the meeting over to Maverick Raber. M. Raber provided an overview of the Water Resources meeting agenda and provided safety moment on "Travel Smart", followed by a summary of the FERC ILP Schedule, and a refresher slide on tasks associated with the Water Resources relicensing study. The meeting's purpose was to cover Task 1 – Summary of Existing Water Quality Data and Standards.

Topic 1 – Lake Jocassee

M. Raber provided a summary of Lake Jocassee physical characteristics, historical monitoring station locations, and submerged weir, and discussed individual water quality parameters for Lake Jocassee (temperature and thermal stratification, dissolved oxygen, conductivity, phosphorous). M. Raber summarized water quality parameters (temperature and DO) in Whitewater River cove and emphasized that patterns of natural stratification are disrupted upstream of the weir due to the Project's inlet/outlet structure, but stratification is present downstream of the weir and the weir is functioning as intended. M. Raber also summarized turbidity data collected in the Whitewater River cove.

Question – Dan Rankin asked about turbidity in the Devil's Fork arm of Lake Jocassee due to the original construction of the Project dams and noted that Devil's Fork was the primary area of Lake Jocassee impacted by turbidity, not the Whitewater River cove. Ty Ziegler stated that turbidity was

increased due to construction of the original dams and there are turbidity data for Howard Creek provided in the forthcoming report.

Question – Dale Wilde asked about turbidity in the Whitewater River cove due to construction activity including the presence of haul roads. M. Raber stated that turbidity would have increased during original Project construction based on everything external (i.e., powerhouse construction, weir construction, dam construction – not just from roads). D. Rankin added on to the discussion and asked about potential impacts (of turbidity and phosphorus) due to construction of Bad Creek II and spoil placement. M. Raber indicated that future impacts would be incorporated into future tasks for the Water Resources study and that that current task (Task 1) is to summarize existing data, however, existing data will be used to inform future tasks (i.e., Task 5, Future Water Quality Monitoring Plan Development).

D. Rankin acknowledged M. Raber's point about future work covered under future tasks asked about the submerged weir and the habitat loss near the submerged weir due to increased turbidity. M. Raber stated that was something that could be discussed at the combined Aquatics and Water resources meeting, scheduled for July 27th.

Question – Dale Wilde inquired about the elevation of the submerged weir, the amount of water over the submerged weir, and if Bad Creek is at full pond, what would be the elevation of the weir.

M. Raber indicated that this exchange of water between Bad Creek and Lake Jocassee will be addressed through modeling (Tasks 3 and 4), however, D. Wilde indicated she just wanted to know the elevation over the weir under various drawdown elevations. T. Ziegler provided the water elevation of Lake Jocassee water surface over the weir at full drawdown (Lake Jocassee at el. 1080 ft, leaving 20 ft of water over the weir crest, which is at 1060 ft; at full pond Lake Jocassee is at el. 1110 ft). D. Wilde asked about how changes in water level would look along the shoreline of Lake Jocassee. Alan Stuart stated it would be a matter of inches – and this will be confirmed under Task 4 (CHEOPs) – and that the worst-case scenario would be less than six inches of elevation difference. A. Stuart indicated that there aren't many inputs into Bad Creek (since it is a very small watershed), and there are Low Inflow Protocol (LIP) rules on how Keowee-Toxaway exchanges water (including exchanges with Bad Creek). T. Ziegler reiterated that Task 4 will fully look at what the changes in elevation are under drawdown scenarios in Bad Creek and Lake Jocassee.

M. Raber added - to address D. Rankin's earlier comment - that future work for Clean Water Act Section 401 and 404 permits would help determine impacts.

A. Stuart mentioned that when compared between Bad Creek I vs. Bad Creek II, impacts from construction will be considerably less for Bad Creek II since dams, roads/infrastructure, etc. are already in place.

Joe Dvorak included hydraulic capacities for Bad Creek in the chat.

M. Raber continued on with the presentation, comparing current day water quality in Lake Jocassee with SCDHEC standards.

Topic 2 – Howard Creek

M. Raber provided an overview of Howard Creek and previous water quality monitoring by Clemson University.

Question – D. Rankin asked about trout put, and grow classification for Lake Jocassee for DO and would Duke Energy consider asking for a site-specific standard for exemption for DO as it's more

meaningful from a management perspective and for the existing MOU. In recent years, under the MOU, 5.0 mg/L is used for the pelagic habitat threshold.

Action Item: M. Raber noted that he will reach out to SCDHEC to clarify assessment methodology and depth of DO samples for State compliance; note Duke Energy's surface measurements are at 0.3-meter depth. Information on assessment methods for State standards as they apply to Project waters will be provided in the Task 1 report, which will be distributed to the Water Resources Committee for review in late June.

John Crutchfield mentioned the combined resources meeting would take place on July 27th in Greenville to discuss Water and Aquatic resources, particularly to discuss the preliminary Water Resources CFD modeling results. The resource committee should expect to receive a "save-the-date" email soon.

M. Raber continued with the Howard Creek overview and compliance with state water quality standards, confirming that most post construction water quality parameters are consistent with pre construction data (within natural variation), and water quality supports high aquatic biodiversity and a healthy fish community, as indicated by the 18-year study carried out on Howard Creek by Duke Energy.

Additional Discussion

D. Wilde asked what was meant by stakeholder engagement process. A. Stuart, J. Crutchfield, and M. Raber indicated that stakeholder engagement was an umbrella term and involved report reviews, meetings, potential additional "ad hoc" meetings to discuss revisions, and anything else that considered stakeholder input.

Adjourn

Action Items

Duke Energy to evaluate DO as it pertains to site-specific exemptions for future monitoring of
aquatic habitat in Lake Jocassee and SCDHEC assessment methodology as it applies to
surface measurements (as opposed to depth measurements) and the percentage of a
dataset that must be considered to classify a waterbody as compliant with State water quality
standards.

2

Safety Moment - Travel Smart

As summertime approaches and days get warmer and longer, many people head out on the road for family vacations, sports team travel, field work, and recreational day trips.

Travel safely through proper planning and sharing!!

- Always communicate your travel plans (with somebody not going!)
- Share your destination, the intended route, and planned arrival time.....and communicate if there's been a change in plans! Always let somebody know when you have arrived.
- Before you go, research road closures/traffic and weather conditions that might affect your trip route and arrival time.
- Have a plan in place in the case of an emergency accident, dead battery, flat tire, etc.
- Travel with plenty of drinking water and a phone charger (and external charger)

Bad Creek Relicensing – Water Resources Study

Water Resources Study - Task Refresher

- Task 1 Summary of Existing Water Quality Data **And Standards**
- Task 2 Water Quality Monitoring in Whitewater River Arm
- Task 3 Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse
- Task 4 Water Exchange Rates and Lake Jocassee Reservoir Levels
- Task 5 Future Water Quality Monitoring Plan Development

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 6

6

Bad Creek Relicensing - Water Resources Study

Task 1 Goals

- Provide sufficient information (through existing data) to support an analysis of potential Project-related effects on water resources.
- Address stakeholder concerns regarding water resources in the Project Boundary with clear nexus to the Project.

Goals will be met through the following:

- Compile & analyze previously collected water quality data from Lake Jocassee and Howard Creek.
- Provide summary of existing data under pre Project and post Project operations to determine Project effect.
- Compare data to SCDHEC state water quality standards.

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 7

7

Lake Jocassee - Overview

- Forms lower reservoir for Bad Creek Project
- Forms upper reservoir for Keowee-Toxaway Project
- Drainage area of 145 square miles
- Duke Energy monitored water quality beginning in the 1970s (12 stations shown on Figure)
- Submerged weir in Whitewater River arm (discussed on next slide)

Lake Jocassee - Submerged Weir

- · During Project construction, excavated rockfill material was hauled to Whitewater River cove, loaded onto on barges, and placed in the water to construct an underwater weir approximately 1,800 feet downstream of the Project inlet/outlet structure.
- The existing submerged weir is approx. 567 ft wide and 455 ft long with a crest elevation of approximately 1,060 ft above mean sea level.
- The weir was installed to help minimize the effects of Project operations on the natural stratification of Lake Jocassee and to dissipate the energy from the Project's inlet/outlet structure.

Lake Jocassee Lakewide Water Quality Data Summary

- Water quality data have been collected since the 1970's by Duke Energy.
- Lake Jocassee water quality data summary parameters:
 - Temperature
 - Dissolved Oxygen Concentration
 - · Dissolved Oxygen Saturation
 - pH
 - · Specific Conductivity
 - Phosphorus
 - Nitrogen
 - · Chlorophyll a
 - Turbidity (Whitewater River Cove only)

Lake Jocassee - Temperature

- Winter temperatures range from 0 to 17°C (32 to 63°F), with an average of 10°C (50°F).
- Spring temperatures range from 5 to 25°C (41 to 77°F), with an average of 11°C (52°F).
- Summer temperatures range from 7 to 30°C (45 to 86°F), with an average of 15°C (59°F).
- Fall temperatures range from 7 to 28°C (45 to 82°F), with an average of 15°C (59°F).

Lake Jocassee - Thermal Stratification

- Lake-wide thermal stratification (i.e., warmer water in the upper water column, cooler water at depth) is less prevalent in the winter months, especially February.
- Stratification begins to form in the upper third of the water column as temperatures continue to warm towards late spring.
- Stratification continues to develop through summer and extends further down into the water column.
- Stratification peaks in early fall and begins to wane as temperatures cool.

Lake Jocassee - Dissolved Oxygen (Standard >6.0mg/L)

- Winter DO concentrations (lake-wide, throughout the water column) range from 0 to 14 mg/L (average 7 mg/L). Average winter surface DO is 9.4 mg/L.
- Spring DO concentrations range from 0 to 13 mg/L (average of 8 mg/L). DO concentrations remain consistent through spring
 months but some stratification is present in the deepest sections of the lake. Average spring surface DO is 9.7 mg/L.
- Summer DO concentrations range from 0 to 13 mg/L (average of 7 mg/L). Stratification becomes more pronounced throughout the lake with the transition from spring into summer. This stratification is generally limited to the lower half of the lake in both deep and shallow areas. Average summer surface DO is 8.2 mg/L.
- Fall DO concentrations range from 0 to 11 mg/L (average of 6 mg/L). The most notable stratification pattern is seen in the fall where the bottom of the lake can reach anoxic levels. DO concentrations remain constant in the top third of the water column, however, significant stratification is observed in the lower water column. Average fall surface DO is 8.1 mg/L.

Lake Jocassee – Dissolved Oxygen Saturation

- The average lake-wide winter surface DO saturation is 87.2 percent. DO saturation remains constant in the upper top half of the lake and decreases from about 80 percent saturation to near anoxic levels at the reservoir bottom.
- The average lake-wide spring surface DO saturation is 98.6 percent. Spring has the highest average DO saturation; spring DO saturation decreases relatively uniformly with depth, with the deepest sections of the lake generally dropping from 100 percent at the surface to 50 percent saturation at the lake bottom.
- The average lake-wide summer surface DO saturation is 101.3 percent. Similar to spring values, DO saturation decreases
 uniformly with depth, but more sharply, generally decreasing from 100 percent at the surface to 35 percent at the lake bottom.
- The average lake-wide fall surface DO saturation is 91.5 percent. As expected, fall continues the trend of decreased saturation in the lower portions of the water column, becoming anoxic near the lake bottom.

Lake Jocassee – pH (Standard = 6.0 - 8.0)

- Lake Jocassee pH ranges between 5 and 10 with an average of 6.2. Low pH values are typical of mountain streams, which tend to be poorly buffered. Waters in Lake Jocassee tributaries also have relatively low pH levels.
- There is very little difference in pH between seasons and while there is some variation in the water column, there is very little to no stratification.

Lake Jocassee - Conductivity

- Conductivity is directly related to rainfall runoff events as tributary inflows to Lake Jocassee carry these dissolved salts and inorganic chemicals from the watershed into the reservoir.
- Since rainfall is fairly consistent through the year in the region, conductivity values in Lake Jocassee do not vary seasonally but do increase during periods of higher rainfall runoff. For example, during drier periods, conductivity in Lake Jocassee is very low ranging from 2.0 to 5.0 µS/cm.
- The overall annual average conductivity in the reservoir was approximately 18.1 µS/cm, with no seasonal trends.

Lake Jocassee – Phosphorus (Standard = >0.02 mg/L)

- Lake Jocassee surface phosphorus concentrations range from 0.002 to 0.65 mg/L over the entire period of record with an average of 0.01 mg/L.
- On average, phosphorus levels were higher after initial filling and have declined over time.
- The highest values are typically nearest tributary inflow.

Lake Jocassee - Whitewater River Cove

- The Whitewater River Cove near Station 564.1 experiences vertical mixing due to the Project inlet/outlet structure – mixing eliminates stratification at this location.
- The submerged weir, which was installed to help minimize the effects of Project operations on natural stratification patterns, confines mixing to the upper portion of the Whitewater River cove.

21

Water Quality Take Home Points

- · Water quality indicates no changes in stratification trend or in overall values b/w pre and post operations in Lake Jocassee EXCEPT for Station 564.1 (due to mixing from the Project discharge).
- The weir is functioning as intended and stratification at Station 564.0 downstream of the weir reflects stratification patterns documented in the rest of the lake.

Whitewater River Cove - Turbidity

- During original Project construction, the Whitewater River cove was directly impacted by construction activities & submerged weir construction. Therefore,
- Data from the three stations in Whitewater River Cove were assessed to determine the following:
 - 1. If an increase in turbidity could be identified & linked to activities or events
 - 2. How far downstream did elevated turbidity impacts extend
 - 3. Length of time turbidity was elevated in the water column
 - · Three time periods were assessed:
 - Pre Construction (<1985)
 - Construction (1985-1991)
 - Post Construction (1992-2015)

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 27

27

Turbidity - Station 564.1

Period	Max Depth (m)	Average NTU	Stdev NTU	Max NTU	Count
Pre construction	N/A	N/A	N/A	N/A	N/A
Construction	45	18.5	51.0	476	480
Post construction	44	0.8	2.0	28	890

- Pre construction: Measurements were not taken until 1988, therefore there is no pre construction dataset
- · Construction:
 - During specific times during the construction period, turbidity was elevated consistently throughout the water column on the same days
 - When elevated turbidity was noted, higher values were in the bottom half of the water column (20-40 m)
 - Average construction turbidity was 18.5 NTU, maximum was 476 NTU (January 1988)
 - Readings were elevated for several readings in a row at the beginning of the construction period, indicating prolonged construction activities
- · Post-construction:
 - Data averaged 0.8 NTU only 7 measurements were above 10 NTU and 6 of these were on the same day

 August 17, 1994 associated with <u>Tropical Storm Beryl</u>.

Bad Creek Pumped Storage Project Water Resources Committee Meeting

29

Turbidity - Station 564.0

Period	Max Depth (m)	Average NTU	Stdev NTU	Max NTU	Count
Pre construction	40	6.6	10	71	382
Construction	74	2.9	5.2	57	545
Post construction	74	0.5	1.2	14	1353

Pre construction:

- The average and maximum turbidity for pre construction is higher than construction and post construction, likely due to recent filling of the reservoir and inflows from tributaries
- Elevated values were episodic and specific to the date the measurement was taken (had returned to baseline during the next measurement) and high turbidity was associated with the same day.

Construction:

- · Turbidity values were lower than pre construction turbidity values overall.
- Elevated turbidity noted at the upstream station associated with construction activities were not noted on the same days at Station 564.0, therefore, elevated turbidity did not extend downstream to this point.

Post construction:

• Turbidities are lower than pre construction and construction – average 0.5 NTU

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 31

31

Turbidity - Station 560.0

Period	Max Depth (m)	Average NTU	Stdev NTU	Max NTU	Count	
Pre construction	60	3	2.9	19	593	
Construction	82	1.5	1.0	13	462	
Post construction	78	0.7	1.0	11.6	621	

- Pre construction:
 - · During the pre construction period, the average turbidity was 3.0 NTU (stdev 2.9) and the maximum turbidity value was 19 NTU. Half of the elevated turbidity values were from a single day on September 12, 1978 (average 13.25 NTU).
- Construction:
 - The construction period average was 1.5 NTU, half of the pre construction average turbidity.
- Post construction:
 - Post construction average NTU is the lowest at 0.7 NTU

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 33

33

Turbidity – Take Home Points

- 1. Under current conditions, average NTU is less than 1.0 NTU at all stations assessed.
- 2. Where data are available, turbidity values were highest during pre construction (likely due to natural fluctuations/rain events from incoming Whitewater River flows).
- 3. All elevated turbidity values occur on the same days and are elevated throughout the water column (not spread randomly over several measurements or at random depths).
- 4. During construction, the elevated turbidity at Station 564.1 upstream of the weir is not observed downstream of the weir.
- 5. Data indicate that, unless there was a prolonged construction activity, elevated turbidity values typically returned to baseline for the following measurement, indicating rapid recovery from elevated values back to normal values (i.e., within one month conservatively).

Period	Location 564.1	Location 564.0	Location 560.0	
Pre construction	N/A	6.6	3	
Construction	18.5	2.9	1.5	
Post construction	0.8	0.5	0.7	

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 34

Whitewater River Cove - Turbidity

- Unlike other water quality parameters, turbidity is not an inherent property of water, however, it can be an <u>indicator</u> of waterbody health.
- Turbidity values increase with increased particles (organic or inorganic) in the water column.
- Turbidity levels in a waterbody are <u>episodic</u> and are <u>not</u> <u>spatially or temporally consistent</u>.
- Under natural conditions, suspended sediment load contribution increases during a rainstorm/runoff event where <u>sediment is eroded</u> from upland areas or stream banks and flows into surface waters. Another major contributor to upland soil/sediment erosion is construction activities.
- Increases in turbidity due to rain or land disturbance are usually short-lived and temporary.

South Carolina DHEC Water Quality Standards

Parameter	South Carolina Water Quality Standard						
Temperature (applies to heated effluents only)	Trout Waters: Not to vary from levels existing under natural conditions, unless determined some other temperature shall protect the classified uses						
Dissolved Oxygen	Trout Waters: Not less than 6.0 mg/L						
pH	Trout Waters: between 6.0 and 8.0						
Turbidity	Trout Waters: Not to exceed 10 NTU or 10% above natural conditions, provided existing uses are maintained.						
Phosphorus	Blue Ridge: Shall not exceed 0.02 mg/L.						

- Lake Jocassee = Trout Put, Grow, and Take (TPGT)
- Howard Creek = Trout Natural Waters (TN)
 - Lake Jocassee is included in the highest water quality classification (i.e., excellent rating) as designated by SCDHEC and preservation of existing conditions is recommended, with most tributaries within the watershed fully supporting their designated use.
 - Lake Jocassee is one of only a few reservoirs in South Carolina possessing the necessary aquatic habitat (water temperatures and dissolved oxygen [DO]) to support both warmwater and coldwater (salmonid [trout]) fisheries year-round.

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 37

37

Lake Jocassee Water Quality Compliance with State Standards

- Temperature (State standard = zero variance from natural conditions) Temperatures in Lake Jocassee consistently met South Carolina water quality standards for trout waters; aside from monitoring location 564.1 immediately downstream of the Project, there are no discernable patterns that would suggest Lake Jocassee temperatures are affected by Bad Creek operations or outside the range of natural conditions.
- Dissolved Oxygen (State standard = >6.0 mg/L) Surface DO measurements (instantaneous) in Lake Jocassee consistently met South Carolina water quality standards for trout waters.
 - Before 1991 there were two instances of surface DO less than 6.0 mg/L: 4.6 mg/L at monitoring location 558.0 in 1973 and 5.4 mg/L at monitoring location 556.0 in 1976, which correspond to the first few years after the reservoir was filled in 1973. There were no instances of surface DO values less than 6.0 mg/L after 1991.
- pH (State standard = 6.0-8.0 mg/L). Lake Jocassee pH ranges between 5 and 10 with an average of 6.2, which is considered neutral and indicative of a system with low production (i.e., low potential for algal growth). Because surface waters in this region are typically poorly buffered and tend to have low pH values, many values were below 6.0 mg/L.
- Turbidity (State standard = 10 NTU maximum). Lake Jocassee average NTU is <1.0 NTU.
- Phosphorus (0.02 mg/L maximum). Instantaneous surface phosphorus readings were compared against the state standard for trout waters. Lake Jocassee surface phosphorus concentrations range from 0.002 to 0.65 mg/L over the entire period of record with an average of 0.01 mg/L. On average, phosphorus levels were higher after initial filling and have declined over time.
- Conductivity There is no state standard for specific conductivity, though concentrations less than 500 µS/cm are generally considered to be suitable for aquatic species in southern Appalachian streams (USEPA 2020). Over the full period record across all monitoring locations, the highest conductivity reading was 275 μS/cm, and the average was 18.1 μS/cm.

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 38

Lake Jocassee Water Quality Compliance with State Standards

- Turbidity In freshwater lakes in South Carolina for trout waters, the threshold is not to exceed 10 NTU (or 10 percent above natural conditions, provided existing uses
- Turbidity data from recent years indicates an average of <1.0 NTU in the Whitewater River cove.

Howard Creek - Overview

- Howard Creek is a tributary to Limber Pole Creek / Lake Jocassee
- Drainage area of 4.3 square miles at confluence with Limber Pole
- Flows in a southeasterly direction immediately downstream of the Project dams and receives seepage from dams (approx. 5.0 cubic feet per second)
- Clemson University monitored water quality before and after Project construction – their results from 1993 are summarized to represent post operational conditions in Howard Creek.

41

Howard Creek Water Quality Data Summary

- Pursuant to Article 34 of the original license for the Project (issued to Duke Power Company in 1977) water quality studies in Howard Creek were carried out to assess impacts to Howard Creek associated with construction and operation of the Project.
- Field data were collected by Clemson University from January 1980 through December 1993 covering pre construction, construction, and post construction.
- Water quality parameters and sampling locations were determined in coordination and agreement with FERC, SCDHEC, and SCDNR.

5 Sampling Locations (Abernathy et al. 1993)

- 1. H/1: Between Corbin Creek and Lake Jocassee
- 2. H/2: Between Limber Pole Creek and Corbin Creek
- H/6: Downstream from the Old Schoolhouse Road and an unnamed tributary entering from the east and upstream from Limber Pole Creek
- 4. H/7: Just downstream from Bad Creek
- 5. H/9: Just upstream of Highway 130 (control)

Howard Creek Water Quality Data Summary

- Baseflow samples were measured monthly in 1993: water temperature, DO, pH, specific conductance, total alkalinity, total suspended solids (TSS), turbidity, 5-day biochemical oxygen demand (BOD₅), fecal coliform, and total hardness.
- Measured on a quarterly basis: ammonia nitrogen, nitrate/nitrite nitrogen, orthophosphate, and total phosphorus.
- Draft report will include tables of all water quality parameters from each station representing existing operating conditions.

Example: Station H/7

Water Quality Baseflow Conditions for Howard Creek - Post Operations (1993)

Howard Creek Water Quality Data - Pre construction vs. Post construction

- Overall, water quality parameters that showed the most change between pre and post construction were total alkalinity, hardness, and specific conductivity at Station H/7, immediately downstream of the dam:
 - Increases in alkalinity, hardness and specific conductivity at H/7 were due primarily to seepage waters through the main and west dams coming into contact with newly placed grout material.
 - These three parameters are also directly dependent on rainfall and water flow.
 - While grout influenced these water quality parameters, fluctuating specific conductivity, water hardness, and alkalinity is a naturally occurring phenomenon/characteristic of Howard Creek.
 - It is expected that these parameters (with the exception of pH) will continue to decline and stabilize.

45

Howard Creek Water Quality Data – Pre construction vs. Post construction

Station H/1 (2015)

Station H/6 (2015)

Station H/9 (2015)

 Results from Abernathy et al. (1994) indicate total suspended solids, turbidity, temperature, DO, pH, BOD₅ and fecal coliform under operational conditions are similar to and fall well within the range of natural/seasonal variation observed under pre operational conditions.

47

Howard Creek Water Quality Compliance with State Standards

- Temperature In post construction data, the warmest temperature recorded above and below the Project on Howard Creek was 20.5°C at station H/2. In pre construction data, water temperatures as high as 21°C were noted. Project operations have not affected water temperature in Howard Creek.
- Dissolved Oxygen Post construction DO measurements are greater than the SC trout water standard, therefore DO is considered to be within state standards for trout waters for Howard Creek.
- pH Mountain streams such as Howard Creek are typically poorly buffered and tend to have low pH values. Low values were recorded in Howard Creek during all phases of sampling and there is also a link between pH decreases and prolonged lack of rainfall.
- Turbidity All measurements were below the state standard of 10 NTU for trout waters.

Bad Creek Pumped Storage Project Water Resources Committee Meeting | 48

Howard Creek – Aquatic Sampling

- Biological and fish community sampling took place in Howard Creek from 1997-2015 to monitor the health of the stream after Project construction; three locations (H/1, H/6, and H/9)
- All locations maintained a consistent level of species diversity over the 18-year monitoring program.
- Results show that Howard Creek currently supports fish populations similar to those found in other southern Appalachian streams, indicating suitable water quality and habitat.

49

Water Resources Study - Next Steps

- Stakeholder feedback from today's meeting will be incorporated into the draft report "Summary of Existing Water Quality Data and Standards".
- Draft report will be distributed to the Water Resources Committee in June for a 60-day open comment period.
- Draft report will be finalized and included in the Initial Study Report to be filed in January 2024.

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Water Resources Committee:

Duke Energy is pleased to distribute the draft report <u>Summary of Existing Water Quality Data and Standards</u> for Resource Committee review. This draft report satisfies Task 1 of the Bad Creek Relicensing Water Resources Study. The deliverable and associated appendices are available on the Bad Creek Relicensing SharePoint site at the following link:

<u>Water Resources Study Reports for RC Review</u>. Duke Energy is requesting a 60-day review period, therefore, please submit all comments by **August 29**th. A confirmation email is kindly requested upon review completion (John.Crutchfield@duke-energy.com).

Important – Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables
 available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore,
 we request all comments be made in the SharePoint Word document. This will eliminate version control issues
 and result in a consolidated document for comment response.
- We <u>strongly recommend</u> opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (circled in red on the screenshot below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to <u>Maggie Salazar</u> for SharePoint access assistance or questions.
- If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page (green bar) of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was

- presented during the kick-off meeting. (Note the tutorial provides an alternative way to open the document in Word either technique works!)
- Finally, please note the report appendices are provided in the folder as a PDF. There is no way to comment on a PDF from SharePoint; therefore, we suggest either making the comment in the Word document with reference to the figure/page number or providing figure comments in a separate email.

Please let Alan Stuart or me know if you have any questions.

Thank you,

John Crutchfield

John,

I downloaded the Water Resources Study Report file and re-uploaded the file with minor grammatical comments. The report was very thorough and detailed the findings of pre- and post construction to the Bad Creek pump station. The data illustrated that there was little if any pre- to post differences in the studied parameters. FOLKS's primary concern still rests in the area of Howard Creek, which is a high value recreational fishing stream and vital to trout habitat. We are confident that Duke Energy will continue to study future impacts should Bad Creek II jumpstation move forward and will mitigate as necessary to preserve the quality of that creek.

Respectfully,

Dale Wilde President, FOLKS

Meeting Summary

Project: Bad Creek Pumped Storage Project Relicensing

Subject: Bad Creek Water and Aquatic Resources Joint Resource Committee Meeting

Date: Thursday, July 27, 2023

Location: Duke Energy Operations Center, Greenville, SC

Attendees (in-person)

John Crutchfield, Duke Energy Elizabeth Miller, SCDNR Alan Stuart, Duke Energy Amy Chastain, SCDNR Jeff Lineberger, Duke Energy William Wood, SCDNR Ethan Pardue, Duke Energy Dan Rankin, SCDNR Paul Keener, Duke Energy Erika Hollis. Upstate Forever

Mike Abney, Duke Energy Sarah Kulpa, HDR Maverick Raber, Duke Energy Joe Dvorak, HDR Kelly Kirven, Kleinschmidt Assoc. Jen Huff, HDR

Alison Jakupka, Kleinschmidt Assoc. Kerry McCarney-Castle, HDR

Eric Mularski, HDR

Attendees (virtual)

Lynne Dunn, Duke Energy Melanie Olds, U.S. Fish and Wildlife Service Scott Fletcher, Duke Energy John Hains, Friends of Lake Keowee Society Alex Pellett, SCDNR Kevin Nebiolo, Kleinschmidt Assoc.

Jeff Phillips, Greenville Water Ty Ziegler, HDR

Introduction

John Crutchfield welcomed participants in the room and online to the Bad Creek Relicensing Joint Water and Aquatic Resources Committee meeting, summarized the meeting agenda, provided a safety moment on heat-related issues, introduced the relicensing studies and study leads, and noted the meeting is being recorded. J. Crutchfield briefly covered the status of the relicensing efforts (ILP schedule) and showed the existing Project Boundary; he then handed the presentation over to Maverick Raber to present an update on the Water Resources Study.

Water Resources Study Update

Tasks 1 and 2

M. Raber provided an update on Water Resources Study tasks and summarized topics for discussion during the morning meeting.

- Task 1 "Summary of Existing Water Quality Data and Standards" report was submitted to the Water Resources Study Resource Committee (RC) on June 30th for a 60-day turnaround.
- Task 2 "Water Quality Monitoring in the Whitewater River Arm" is ongoing; M. Raber summarized instrumentation deployment in late May and data collection (every 2 weeks and

every 2 meters vertical profile). Continuous temperature monitoring is underway in the Whitewater River arm at stations 564.1, 564.0, and 560.0. Four elevations are being monitored for dissolved oxygen and temperature to determine flow patterns and how flow/mixing is affected by the existing submerged weir. Water quality data in the Whitewater River cove will be collected during summer 2023 and 2024 to represent conservative (higher temps) conditions under current operations (2023) and planned upgrades at the existing Bad Creek Project (2024).

Task 3

Joe Dvorak introduced modeling efforts for Task 3 of the Water Resources Study "Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse" (CFD Modeling in the Whitewater River Cove), the objectives of the study, and noted results are preliminary. He described how a 2-D model was developed first to determine the model extent for CFD modeling; he described CFD model assumptions and domain as well as existing and proposed weir configurations and typical exceedance water elevations for Lake Jocassee over the period of record. J. Dvorak noted all effects of the additional powerhouse are limited to the model domain which accounts for about 11 percent of the total volume of Lake Jocassee. He provided slides showing figures of preliminary CFD modeling results and indicated full results will be provided in the report to be provided this fall.

Participant Discussion and Questions Tasks 1 - 3

- John Hains (via chat) asked, "What are the criteria for "negligible"? This is in reference to language on Slide 15: "Of the "bookend" scenarios analyzed, combined Bad Creek and Bad Creek II operations (39,200 cfs) with Lake Jocassee at minimum pond elevation (1,080 ft msl) was found to have the greatest effect on Whitewater River Cove hydraulics, however at the downstream model boundary that effect was negligible." J. Dvorak replied there are no stated criteria for "negligible" as it is subjective, but today's discussion will include more about the actual results and the effect of the second powerhouse and conclusions will support this statement.
- Elizabeth Miller asked about the orientation of Slide 17. J. Dvorak explained where the I/O structure was and orientation to the lake.
- Alan conveyed a question from Erika Hollis, who asked if this information has yet been
 presented anywhere. J. Dvorak responded that this is the first time these results are being
 presented. A draft report will be issued soon which will provide detail on the overview
 covered during the presentation.
- Dan Rankin commented that from the results we are seeing (i.e., no effect at the
 downstream model domain due to expanding the weir or adding a second powerhouse), the
 main purpose of the weir is primarily to provide a place to dispose of excavation material. J.
 Dvorak agreed expanding the weir would have limited effects on velocities. D. Rankin then
 asked if any consideration has been given to creating another weir? J. Dvorak responded
 that has not been considered but the model has the capability to evaluate other designs.
- Joh Hains (via chat) asked, "Is there any reason that the expanded weir could be expected to change the velocity field at that downstream location?" J. Dvorak indicated we would get into that specifically later in the slides.
- Gerry Yantis asked if water temperature affects CFD modeling or if temperature/other criteria
 were considered. J. Dvorak indicated there are other parameters CFD model can evaluate
 like temperature, but we have not done that the focus here is solely on hydraulics. M.
 Raber added ongoing data collection efforts in the Whitewater River cove for water quality

- parameters (Task 2) supports the modeling effort to help determine mixing effects upstream and downstream.
- William Wood asked about water flow effects from the Thompson River. J. Dvorak indicated
 even at minimum pond, as you get further into the main body of the lake (downstream of
 Thompson River), flow from the Thompson River has a negligible effect on overall flow
 patterns in the lake.
- Ty Ziegler (via chat): "There are some very minor differences in flow patterns/velocities from
 the existing weir to the expanded weir (mostly at maximum drawdown), but by the time you
 get to WQ monitoring location 564.0, the results are similar. Therefore, we shouldn't see any
 differences in vertical mixing/stratification at location 564.0. Joe will have some figures to
 demonstrate."
- Alex Pellet (via chat): "This is off-topic at the moment, but perhaps we can circle back. I'm
 curious to understand one of the questions, I believe was from Dan Rankin. If disposing of
 the rock material is a goal of this, and there are only marginal benefits to weir expansion,
 then we might prefer other configurations of the material which provide superior aquatic
 habitat? Is that correct?"
 - J. Dvorak discussed the shape of the proposed expanded weir is simplified in the model. The length of the crest of the weir drives model results, not the composition of the weir. He deferred to M. Raber to discuss habitat effects of different materials. M. Raber noted that due to temperature density, when water comes across the weir, flow is laminar across the top, and stratification is not affected downstream of the weir (not affected by mixing upstream of the weir) so the geometry of the weir shape wouldn't change that. Would there be a configuration that would provide more/better fish habitat provided? J. Dvorak indicated there is at minimum 20 feet of water over top of the weir keeping flow at the top therefore, roughness of the surface of the crest of the weir would not affect anything.
- A. Stuart stated all Duke Energy lakes have an established minimum clearance for lake structures due to recreation, however, he does not know the exact depth for Lake Jocassee.
 Dan Rankin asked how often lake was at that minimum depth.
 - Mike Abney confirmed Duke Energy Lake Services has a minimum required depth between a structure placed in a lake (e.g., for fish habitat) and the normal minimum lake elevation. That minimum depth varies by lake and is 50 feet from full pool for Lake Jocassee).
- D. Rankin (Slide 55) asked if the size of the mixing zone downstream of the weir simply would double in length (downstream) by expanding the weir. J. Dvorak replied it's not possible to compare full to minimum pond in these mixing scenarios; it's actually an additional 200 feet downstream due to the expanded weir, not doubled.
- E. Miller (Slide 55) asked if flowlines were forming a loop downstream of the weir? J. Dvorak said it's possible but there are about 500 flow lines so it would be impossible to determine; the reason for the flow path (shown on Slides 50 through 55) is due to the natural thalweg of the flow through Whitewater River cove. M. Raber indicated the flow there is about 0.5 fps in the water column, even under worst case conditions (i.e., minimum pond, generation, two powerhouses, expanded weir).
- Lynne Dunne (virtual): Will there be additional operations requests for Bad Creek for ADCP validations for CFD modeling? A. Stuart answered we will not know if additional schedule changes will be necessary until HDR confirms if the data collected under generating and pumping at the five transects is good. (HDR collected ADCP flow data at 5 transects two weeks prior to the meeting, therefore validation data analysis is forthcoming).

Task 4 - CHEOPS

Ed Bruce opened the Task 4 "Water Exchange Rates and Lake Jocassee Reservoir Levels [CHEOPS Modeling])" discussion, summarizing study objectives and goals for today.

A. Stuart clarified there is no proposed change in the volume/capacity of Lake Jocassee associated with Bad Creek II; E. Bruce noted a good analogy is putting a bigger faucet on a bathtub, but it's still the same bathtub.

E. Bruce reviewed the CHEOPS scenarios (baseline and with Bad Creek II). He noted that as an assumption, the second powerhouse would be available immediately (in the model runs), looking at maximum possible change scenarios and determining if there are any effects noticeable statistically and over time. The performance measures will run for X amount of years and determine any long-term effects and handed over the presentation to Jen Huff to explain more about performance measures.

J. Huff distributed a proposed performance measures spreadsheet to the group (emailed to virtual attendees) and described what performance measures are (i.e., statistical summary of how the model performs for a particular measure), provided definitions of terms, and went through individual performance measures considered in this effort.

Erika Hollis asked about the "MISC" (minimum increment of significant change). J. Huff indicated the MISC is a value that was determined by the Operations Resource Committee (RC) formed for Keowee-Toxaway (KT) relicensing. The MISC for each measure indicates what variance from the baseline result for that measure great enough to represent a statistical difference in results. Using output from KT relicensing, J. Huff walked through what each color meant: cells with no color are not significantly different from baseline, green cells have better results than the baseline, and red performed poorer than baseline conditions. For Bad Creek, Duke Energy is proposing to use the measures used for KT relicensing for Jocassee and Keowee (i.e., nothing further downstream).

J. Crutchfield mentioned the performance measures spreadsheet will be on SharePoint for comments; J. Huff asked for comments by August 15 (comments include any proposed new measures) and requests for those proposing new measures, provide details on the measures requested.

Sarah Kulpa asked if the MISC is for the license year or just the number of times something occurs during the entire period of record. E. Bruce noted it could be for either, depending on the measure. S. Kulpa asked J. Huff to describe the philosophy of developing the MISC and asked if there is a benefit to using the same MISC that was developed for KT relicensing. J. Huff indicated the period of record that will be used for Bad Creek runs is the same as was used for KT relicensing (unimpaired flow data from same days and modeled over same number of days), so believes the MISCs to be appropriate. She also stated there was a lot of time and effort dedicated to developing the measures and MISCs during KT relicensings. E. Bruce indicated if stakeholders believe there should be a change to the MISC, the RC is welcome to suggest revisions. J. Huff reiterated the model cannot be run until performance measures are assigned.

E. Miller noted the SCDNR would like to see performance measures 8-19 and (maximum spawning success for black bass and blueback herring) and 42-53 (maximize spawning success for sunfish and threadfin shad) revised. Measures 8-13 and 42-47 should extend through the end of May (currently extend from April 1 through May 15).

- A. Stuart asked for clarification on the MISC would SCDNR want to keep the MISC at 10%. E. Miller indicated 5% might be better for the MISC (5% of the years over the period of record). W. Wood asked for clarification on the MISC J. Huff indicated 10% means 10% of years where it remains within the prescribed range. SCDNR proposed changing the MISC to 5% for measures 8-25 and 42-57.
- J. Huff reviewed performance measure example of spawning elevation using KT example on Slide 68. Difference between baseline/scenario calculation and the MISC (variance).
- D. Rankin sought clarification that Bad Creek cannot change the KT license and J. Huff confirmed.
- D. Rankin noted the PMs may not be adequate to represent fish spawning due to the spawning period having a bell-shaped curve with peak success occurring in the middle of the season. He indicated the measure would more accurately capture success with a tighter time period, not longer, to capture this.
- J. Huff indicated the thinking is that if there is at least one X-day period in spawning season, there would be some spawning success. Spawning seasons shift year-to-year and will continue to do so with climate change. Jeff Lineberger noted the same conversation occurred during KT relicensing.
- J Lineberger reminded the group that the CHEOPS model does not address water quality or factors other than lake levels. E. Bruce and J. Lineberger further described parameters for CHEOPS and future with Bad Creek exchanging water differently than occurred 15 years ago.
- J. Huff asked if it would be helpful to provide the performance measures from KT out from the spreadsheet. E. Hollis indicated it might be helpful.
- A. Stuart noted if an RC member would like to suggest a performance measure but is not sure exactly how to provide that information, Duke Energy will help. J. Huff agreed.
- D. Rankin asked for time to think about parameters for this project vs. SCDNR/Army Corps of Engineers previous parameters for KT relicensing; SCDNR also requests time to review performance measures. J. Huff offered to have a conversation offline if that would be helpful.
- A. Stuart asked D. Rankin if his concerns are related to both Jocassee and Keowee. D. Rankin indicated there was only one year of recruitment issues at Keowee and that was during a maintenance drawdown so he does not believe recruitment issues would extend downstream to Lake Keowee. However, he feels it would be more conservative to include and would like Keowee considered.
- J. Crutchfield and A. Stuart asked if the RC agreed with and could provide confirmation/comments on performance measures by August 15th. Erika Hollis asked if comments need to be formal; J. Huff indicated it could be in any format, including comment bubbles on the spreadsheet provided on SharePoint or simply an email.
- A. Pellett (via chat): "When natural resources performance measures "maximize spawning success", are we saying the fluctuation bands and numbers of consecutive days are sufficient to maximize spawning? Or, should I understand these to be "tolerable" or "sufficient to maintain populations?" I'm not suggesting that we necessarily need to maximize this specific factor (lake elevation) for spawning, I just want to understand the metric as well as I can. I'm not a fish expert... I think Dan just clarified that a bit actually..."

- A. Pellett indicated (via phone) his concern had been answered during the discussion.
- J. Huff thanked the group for the discussion and closed the Water Resources Study discussion.

<<15-Minute Break>>

Aquatic Resources Study Update

Mike Abney provided an overview of study status including updates on the entrainment study (Task 2 – Consultation on Entrainment) as well as Task 3 (Mussel Surveys and Stream Habitat Quality Surveys). M. Abney mentioned that Nick Wahl and others from Duke Energy are currently in the field for Task 3 efforts. He then introduced the two options for the potential access road proposed by Duke Energy for access to the Fisher Knob community during construction, showed the potential spoil locations (to store spoil from excavations for new structures, and briefly introduce the methodology that will be undertaken in response to requests from the SCDNR (i.e., use of SC Stream Quantification Tool [SQT]).

- E. Miller asked about SQT for small streams near spoil sites. M. Abney briefly stated there was a recent field visit with Duke Energy/HDR/SCDNR to inspect two of the representative spoil locations and discussions during the presentation will circle back to the SQT. Mussel surveys will be carried out at stream crossings but not spoil areas. Streams in spoil areas and crossed by the access road were evaluated for potential mussel habitat, however, only Howard Creek and Limber Pole Creek were determined to potentially support habitat with concurrence by the SCNDR during the July 12 site visit. Only those two creeks will be surveyed for mussels in addition to the shoreline of Lake Jocassee. M. Abney indicated surveying methods stated in the approved Study Plan will still be carried out, but the SC SQT will be implemented for the larger streams (e.g., Howard Creek, Limber Pole Creek) at potential stream crossings; he then showed field studies schedule.
- D. Rankin asked if roads would be temporary and what would they be constructed with (i.e., gravel?) and asked for clarification on use. A. Stuart indicated they would be temporary, and the hope is to gravel as much as possible, however some slopes may require a hardpan treatment. The primary reason for the road would be to provide access to the Fisher Knob community to their homes during construction.
- W. Wood asked for confirmation that the bridges would be removed following construction and the roads/area blocked off so people cannot continue to access areas (for off-roading). A. Stuart confirmed.
- D. Rankin asked about the design of the road crossings as there are significant differences on aquatic resources in the design of road crossings. A. Stuart acknowledged there could be different effects based on the two road route options given Option 2 (Slide 74) parallels Howard Creek, potentially resulting in more impacts. Duke Energy is leaning towards Option 1 to minimize impacts to the extent feasible. A. Stuart stated the road is still being designed, but he would ask the team for additional details about the design.
- D. Rankin asked if there have been field surveys conducted along the potential road routes. A. Stuart indicated the routes follow old logging roads to minimize impacts. Eric Mularski indicated a wildlife survey will be carried out for potentially listed species along the potential access road routes, so there will be a more complete dataset available of natural resources in these areas.
- J. Crutchfield asked Alison Jakupka and Kevin Nebiolo (Kleinschmidt Associates) to provide an update on the entrainment study. Kleinschmidt has worked with Duke Energy to obtain water quality

and operations data from 1991-1993. The entrainment report draft has now been revised to remove the swim speed analysis as suggested during earlier meetings and incorporate new data. K. Nebiolo reviewed progress that has been made on the entrainment task in light of new data. He noted that entrainment increases with a decrease in Jocassee elevation.

A. Stuart asked for clarification that entrainment discussions are focused on pumpback (not generation). K. Nebiolo agreed that is the case.

D. Rankin and W. William asked for clarification on which units are upstream/downstream first/on first off. A. Stuart clarified the Bad Creek units are numbered 1-4 moving from upstream to downstream.

A. Stuart asked A. Jakupka when the RC can expect the revised entrainment report. K. Nebiolo responded – he projects end of August for new report (to Duke Energy for review) with an RC review comment period following.

E. Miller asked about relocation of the existing wastewater settling ponds. A Stuart indicated the ponds will be replaced separate from relicensing. E. Miller asked if impacts would be assessed prior to clearing a new location. A. Stuart indicated he did not think the location for the new treatment system will require clearing for new basins.

J. Crutchfield concluded the meeting by thanking attendees for their participation and reviewing the action items.

Action Items

- HDR/Duke Energy will post meeting notes, recording, and presentation to SharePoint site and distribute the link to Water Resources and Aquatic Resources RCs.
- HDR/Duke Energy to provide a SharePoint link to the CHEOPS model performance measures; requested deadline for RC comments is August 15. [If needed, HDR/Duke Energy will schedule a follow-up meeting with RC regarding potential revisions to performance measures].
- Potential revisions to CHEOPS performance measures include measures 8-19 and 42-53 and would include changing MISC from 10% to 5% and extending the date from May 15 to May 31. Suggested revisions (by the SCDNR) are on hold subject to further review; SCDNR (and others) to have a closer look and provide comments and feedback by August 15.
- HDR/Duke Energy to post KT performance measures to the SharePoint site and distribute link to RCs.
- HDR/Duke Energy is currently preparing a technical memo regarding stream surveys and will
 post to the SharePoint site.
- Duke Energy to discuss and provide clarification on road and bridge design for access road.

Bad Creek Pumped Storage Project No. 2740

Joint Aquatic and Water Resources Committee Meeting

JULY 27, 2023

1

Meeting Agenda

- Welcome and Meeting Purpose
- Safety Moment
- Introductions and FERC ILP Schedule
- Water Resources Study Update
 - Overview of Tasks
 - CFD Model Discussion
 - Preliminary Results
- Break (15 min)
- CHEOPS Discussion and Performance Measures
- Aquatic Resources Study Update
 - Revised Entrainment Study Report
 - Mussel & Stream Habitat Quality Surveys
- Action Items

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 2

Safety Moment - Heat Safety

- **Tips for Keeping Cool**
 - · Drink water (even if you aren't thirsty). Rule of thumb when working in heat is 1 gallon per 4 hours!
 - Avoid alcohol and caffeine
 - Wear sunscreen (even a mild sunburn can affect the body's ability to cool properly!)
 - Try to schedule outdoor optional outdoor activities for the early morning or evening; if you must work during the day, rest and find shade
 - · Wear loose, light-colored clothing.
- Know the difference between Heat Exhaustion and Heat Stroke.
- Heat Stroke is a MEDICAL EMERGENCY that can lead to death if not treated quickly.

Water Resources Study

Task Refresher

- Task 1 Summary of Existing Water Quality Data And Standards
- Task 2 Water Quality Monitoring in Whitewater River Arm
- Task 3 Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse (CFD Modeling)
- Task 4 Water Exchange Rates and Lake Jocassee Reservoir Levels (CHEOPS Modeling)
- Task 5 Future Water Quality Monitoring Plan Development

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 8

Water Resources Study

- Task 1 Summary of Existing Water Quality Data and Standards
 - Objective: Compile previously collected water quality data and provide a summary of existing data from Lake Jocassee and Howard Creek under current Project operations and prior to Project operations, while addressing stakeholder concerns.
 - Status: The draft report was uploaded to the SharePoint site on June 30 for a 60-day review period.

SUMMARY OF EXISTING WATER QUALITY AND STANDARDS

DRAFT REPORT

WATER RESOURCES STUDY

Bad Creek Pumped Storage Project FERC Project No. 2740

Oconee County, South Carolina

June 30, 2023

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 9

9

Water Resources Study

- Task 2 Water Quality Monitoring in Whitewater River Arm
 - Objective: Collect continuous temperature data and periodic DO (bi-weekly) from three historical locations in the Whitewater River Cove to gather current-day representative (i.e., baseline) water quality information in Summer 2023 and 2024.
 - · Status: Ongoing.
 - Dataloggers were deployed May 22nd and 23rd.
 - Four data collection trips have been made and will continue every two weeks through September.

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 10

Water Resources Study

- Task 3 Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse (CFD Modeling)
 - Objectives
 - Use a two-dimensional (2-D) hydraulic model to determine the downstream extent of potential effects (i.e., mixing) in the Whitewater River Cove due to an additional powerhouse (Bad Creek II).
 - Develop CFD model to evaluate flows and extent of vertical mixing in the Whitewater River arm and downstream of the submerged weir due to the addition of Bad Creek II.
 - · Status: Ongoing.
 - · Simulations are complete and analyses are ongoing.
 - Velocity data were collected in mid-July along 5 transects in the Whitewater River cove with boatmounted ADCP for ongoing model validation.

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 13

13

Task 3 – Introduction to Computational Fluid Dynamics

- · Modeling software capable of solving complex hydraulics in three dimensions.
- CFD models solve the three-dimensional form of the Navier-Stokes equations that govern fluid momentum in conjunction with conservation of mass (continuity).
- Commercially available Flow-3D software used for the Bad Creek analysis.

Task 3 – Modeling Steps and Take-Home Message

- 2-D hydraulic model (Innovyze) was developed to help determine the downstream modeling extent (model domain) required for the CFD model.
- 2. CFD model was developed to evaluate hydraulic effects (depth, velocity, flow patterns) of Bad Creek II operations on vertical mixing in the Whitewater River cove.
- 3. Sixteen scenarios were evaluated using pumping and generating modes under existing and proposed conditions (including potentially expanded weir).

Take home message: Of the "bookend" scenarios analyzed, combined Bad Creek and Bad Creek II operations (39,200 cfs) with Lake Jocassee at minimum pond elevation (1,080 ft msl) was found to have the greatest effect on Whitewater River Cove hydraulics, however at the downstream model boundary that effect was negligible.

Lake Jocassee Area (full pond): 7,980 acres Modeled Area (full pond): 2,840 acres

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 15

15

Task 3 – 2-D Modeling [Innovyze ICM]

- CFD modeling requires lengthy computing time, therefore 2-D model was used to quickly determine the approximate CFD modeling extent (modeling boundary).
- 2-D model terrain based on previously gathered Lake Jocassee bathymetry and SC State lidar.
- Scenarios assume full generation/pumping capacity for the entirety of the simulation.
- Simulation length was determined by the time it takes to drain/fill Bad Creek from full pond to maximum drawdown.
- · 2-D modeling is depth-averaged.

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 16

Task 3 – CFD Model Development

- Model domain extends just upstream of confluence with Devil's Fork Arm.
- Inflows and water surface elevations held constant at the inflow boundary.
- · Maximum generating/pumping capacity simulated.
- Thompson River flow included (long term average flow).
- · Two pond levels modeled.
- · Two weir geometries modeled.

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 18

Task 3 – CFD Model Geometries & Scenarios

47

Effect of Submerged Weir Geometry during Generation

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 48

Task 3 – Initial Conclusions from CFD Modeling

Generation

- The energy of the water discharged from Bad Creek is dissipated as it's forced up and over the existing submerged weir.
- · Similar vertical mixing and flow patterns result from flows over existing and expanded weir.
- Similar vertical mixing and flow patterns result from Bad Creek II powerhouse operations.
- Results indicate Bad Creek II powerhouse operations will not alter existing stratification patterns observed at Station 564.0 (downstream of weir).

Pumping

- Hydraulic impacts due to Bad Creek II pumping impacts limited to Whitewater River Cove upstream of submerged weir.
- Pumping in any configuration does not create mixing downstream of submerged weir.

**Draft Report will be distributed in the fall for Resource Committee review

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 63

63

Water Resources Study

Task 4 – Water Exchange Rates and Lake Jocassee Reservoir Levels (CHEOPS Modeling)

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 64

Task 4 – Water Exchange Rates and Lake Jocassee Reservoir Levels (CHEOPS Modeling)

Goals for today:

- Initial CHEOPS performance measures
- Modeling scenarios
- · Update on model refinement

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 65

65

Task 4 – Performance Measures

· Objectives:

- Use the existing CHEOPS model to evaluate the difference in water <u>exchange rate, frequency</u>, <u>and magnitude</u> between Bad Creek Reservoir and Lake Jocassee due to the addition of a second powerhouse.
- Identify and evaluate impacts, if any, to Lake Keowee as a result of operating an additional powerhouse at the Project.

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 66

Task 4 - CHEOPS Scenarios

Baseline:

- · Existing Bad Creek powerhouse
- · Existing Bad Creek license
- KT license
- · Updated demand curve (Bad Creek and Jocassee)
- Updated pumping dispatch curves (Bad Creek and Jocassee)
- Updated weekly drawdown cycle (30,000 ac-ft)

Bad Creek II:

- Baseline plus:
 - 4 Bad Creek II units (identical to existing units)
 - Pumping dispatch curve (Bad Creek II)
 - Assumption: Bad Creek II available for the entire scenario run

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 67

67

Bad Creek Pumped Storage Project Joint Resource Committee Meeting | 68

Task 4 – Bad Creek Performance Measures

- Starting Point: KT Relicensing Performance Measures
 - All Jocassee and Keowee lake level measures & LIP Stages
 - New measure: Measure 7 Number of days where Jocassee reservoir level changes more than 1.0 ft in one hour
 - Revised measures
 - Measure 59 Number of days where Keowee level below critical level (790.0 ft msl) for thermal power operation
 - Measures 61-66 Number of days in LIP Stages; added MISC

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 69

69

Aquatic Resources Study

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 70

Task 1 – Consultation on Entrainment

Draft Entrainment Study Report

- Meeting with the Aquatic Resources RC in April 2023
- Entrainment study evaluating additional parameters affecting entrainment scenarios
 - Lake surface elevation (+/- 1,099 ft msl; 89 ft)
 - · Water temperature
 - Hours of pumping (day vs night operations)
- Distribute draft study report by November 2023

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 71

71

Task 2 – Desktop Studies on Potential Effects to Pelagic and Littoral Habitat

- Meeting with the Water Resources RC in July 2023 (today)
- · Water Resources Study modeling results
 - 2-D hydraulic model
 - CFD model
 - CHEOPS model
- Discuss desktop study results in early spring 2024

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 72

Task 3 - Mussel Surveys and Stream Habitat Quality Surveys

Potential Spoil Locations

- Mussel surveys
 - Late July: survey of Lake Jocassee shoreline in the vicinity of Bad Creek inlet/outlet and submerged weir
 - · Mussel habitat is not present at upland potential spoil locations
- Stream habitat assessments
 - NC Stream Assessment Method (NCSAM) and USEPA Rapid Bioassessment Protocol (RBP) will be completed for all streams within potential spoil locations

73

Task 3 – Mussel Surveys and Stream Habitat Quality Surveys

Potential Access Road

- Fish Community & Mussel surveys
 - **Howard Creek**
 - Limber Pole Creek
- Stream habitat assessments
 - All streams crossed by the potential access road
 - NCSAM + USEPA RBP
 - SCDNR Stream Quantification Tool (SQT)

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 74

Task 3 – SCDNR Consultation

- May 2023: SCDNR requested that Duke Energy use the Stream Quantification Tool (SQT) to evaluate streams potentially impacted by Bad Creek II Complex construction activities
- May 24 and June 21, 2023: consultation calls held with SCDNR regarding SQT methodology and applicability
- July 12, 2023: site visit with Lorianne Riggin (SCDNR) to streams within two potential spoil locations
- ➤ A memo is under development which will include a summary of the survey approach for streams within potential spoil locations and along the potential access road.
- Methods described in the RSP still apply.

Bad Creek Pumped Storage Project Joint Resources Committee Meeting | 7

75

Task 3 - Mussel Surveys and Stream Habitat Quality Surveys

SCDNR Stream Quantification Tool

- Used to assess functional lift or loss from an action
- Based on five functional categories
- Function-based parameters
 - Reach runoff
 - Floodplain connectivity
 - Flow dynamics
 - · Large woody debris
 - Lateral migration/erosion
 - Riparian vegetation
 - Bed form diversity
 - Biology dependent on drainage area
 - Fish community
 - Macroinvertebrates

ad Creek Pumped Storage Project Joint Resources Committee Meeting | 7

Task 3 – Mussel Surveys and Stream Habitat Quality Surveys

Field Studies Schedule

Task	Location(s)	Timeframe
Fish community sampling*	Potential access road	Late July - October (3 events)
Mussel surveys*	Lake Jocassee & Potential access road	Late July
Macroinvertebrate sampling*	Potential access road	Early August
Stream habitat assessments (NCSAM + USEPA RBP)*	Potential spoil locations & potential access road	Early-mid October
Stream geomorphic surveys and riparian vegetation assessments	Potential access road	Early-mid October

^{*}Incidental observations of amphibians and reptiles will be documented.

65		Number of days in LIP Stage 3	1-Jan	31-Dec	10	
66		Number of days in LIP Stage 4	1-Jan	31-Dec	10	

Notes	
	For criterion that measure on an hourly or daily basis, unless stated otherwise:
	a. If an hourly criteria occurs during the average of four contiguous 15-minute periods, then it counts as 1 hour.
1	b. If a daily criterion occurs for 5 contiguous 1-hour periods, then it counts as 1 day.
	Also, daytime flows are assumed to be flows provided between 7:00 am and 7:00 pm. To the extent possible, each criterion is defined in terms of percents and averages/yr so that the same criterion is useful regardless of the length of
	the hydrology period (i.e., 1-yr, 3-yr, full period of record, etc.)
	MISC = Minimum Increment of Significant Change. The MISC has the same units (i.e., days, days/yr, percent, etc.) as does the criterion on that same row of the spreadsheet. If the output of two scenarios for a particular criterion differs
	by less than or equal to the MISC, then there is no significant difference between those two scenarios as far as the criterion in question is concerned. The following guidelines were used to establish the MISC numbers:
2	a. As a general rule, MISC numbers are set at 10% of the possible total for that criterion considering the Start/Stop dates.
	b. MISC numbers for criteria that have the most adverse outcomes if reached are typically set at less than 10% of the possible total for that criterion.
	c. Adjustments to the MISC numbers (up or down) have also been made depending on the desires of the stakeholders that primarily have the interests that are being measured by a particular criterion.
3	Jocassee restricted recreation elevation 1,090 ft AMSL provided by Chris Starker (Upstate Forever) and confirmed by Devils Fork State Park Staff.
4	Jocassee elevation 1,077 ft AMSL is the lowest boat ramp elevation with an additional 3 ft added for boat access. Boat ramp elevations provided by Duke Energy.
5	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.

DRAFT - 7/28/2023

6	Jocassee entrainment elevation (1,096 ft AMSL) provided by Bill Marshall of SCDNR.
7	Jocassee fish habitat elevations provided by Bill Marshall of SCDNR.
	Jocassee elevation 1,099 ft AMSL is the elevation at which an MOU between Duke Energy and SCDNR requires Duke Energy to implement operational changes at Bad Creek. Jocassee elevation 1,090 ft AMSL is the elevation at which
8	Jocassee powerhouse efficiency is degraded.
9	Jocassee elevation 1,081 ft AMSL provided by Duke Energy based on impact to pumping equipment.
10	Keowee restricted recreation elevation of 792 ft AMSL provided by James McRacken (HDR) and Scott Fletcher (Duke Energy).
11	Keowee elevation 790 ft AMSL is based on the lowest boat ramp elevation of 787 ft AMSL plus 3 ft for boat access (provided by Duke Energy).
12	Percent of time is measured as the percent of 15-minute time steps at or above threshold elevation during period starting 07:00 am and period ending 7:00 pm.
13	Toe of Keowee reservoir riprap elevation 794 ft AMSL provided by Duke Energy.
14	This criterion evaluates a day as 24 contiguous hours, not as specified in Note 1.
15	Keowee fish habitat elevations provided by Bill Marshall of SCDNR.
16	Keowee elevation 775 ft AMSL was the minimum level permitted in the previous KT FERC License, and the Keowee water supply intakes present during KT relicensing were confirmed to operate at this reservoir level.

Subject: RE: Bad Creek Relicensing-- CHEOPS Performance Measures Discussed at July 27 Joint Resource Committees

Meeting

Importance: High

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Resource Committee Members:

Thank you for your participation in discussing the proposed CHEOPS performance measures (PM) during our recent July 27 joint resource committees meeting. We will use the PMs for the CHEOPS modeling for the Bad Creek relicensing.

Note this email is being sent to the Aquatics, Water, Recreation & Visual Resources, and Operations Resources Committees members for review and comment.

The PMs are now posted on the SharePoint site here: <u>Bad Creek Relicensing Project – Resource Committees - CHEOPS Performance Measures - All Documents (sharepoint.com).</u>

When you access the site, you will find three files:

- The PMs we reviewed in hard copy format last Thursday.
 - These reflect minimal changes from the PMs used during Keowee-Toxaway (KT) relicensing.
 - The changes from KT relicensing are highlighted in yellow.
- The PMs as potentially revised during our discussion.
 - o The changes discussed by SCDNR during the meeting are highlighted in orange.
- A PM sheet from KT relicensing.
 - This is intended to help you understand how the MISC (minimum increment of significant change) informs the color coding.
 - Scenario results are compared only to the "Baseline CC Low" results.
 - Remember if the cell is not red or green, that means the MISC wasn't met and there's no significant difference between the results for the scenario and the baseline for that particular measure.
 - o The period of record (i.e., the timeframe) for the model is 1939-2011 which equates to 73 years.

As a reminder, we need input as to changes you would like to see by <u>August 15</u> so we can move forward with the modeling. You can provide your input via email to Alan Stuart and me.

Please let Alan or me know if you have questions and thank you for your continued participation in the Bad Creek relicensing.

Regards,

John Crutchfield

Meeting Summary

Project: Bad Creek Pumped Storage Project Relicensing

Subject: CHEOPS Performance Measures Meeting Summary

Date: Thursday, August 17, 2023

Location: Microsoft Teams

Attendees (virtual meeting)

John Crutchfield, Duke Energy Alan Stuart, Duke Energy Ed Bruce, Duke Energy Jen Huff, HDR Kerry McCarney-Castle, HDR

Elizabeth Miller, SCDNR Amy Chastain, SCDNR Scott Harder, SCDNR Alex Pellett, SCDNR William Wood, SCDNR

Dan Rankin, SCDNR

Introduction

John Crutchfield welcomed participants and opened the meeting. The meeting's purpose is to discuss CHEOPS performance measures for Bad Creek Pumped Storage Project relicensing and was requested by the South Carolina Department of Natural Resources (SCDNR). J. Crutchfield noted the discussion would be recorded and a written summary would be compiled and distributed. He also provided a safety topic on schools back in session and be mindful of children at bus stops and traffic near schools.

CHEOPS Performance Measures

Elizabeth Miller began the discussion by noting most of their questions revolved around what the "Baseline" would be on some of the performance measures. J. Huff shared her screen and displayed the table of performance measures shared with the Water and Aquatic Joint Resource Committee (RC) during the July 27th meeting. The baseline (column G) will be modeled output from the baseline scenario. The baseline scenario is based on the Keowee-Toxaway (KT) relicensing scenario, so it includes KT license requirements. It also includes upgraded Bad Creek units, an updated Bad Creek reservoir storage volume curve, and new energy dispatch curves associated with operational changes. The CHEOPS model will determine over the period of record how many times the value in question is above or below each criterion. J. Huff shared a completed performance measure sheet from KT relicensing to demonstrate how "baseline" results are displayed.

Ed Bruce reiterated the baseline scenario used for KT relicensing has different model settings than the baseline scenario that will be used for Bad Creek relicensing. These differences include settings related to the upgraded Bad Creek units, an updated Bad Creek reservoir storage volume curve, and new energy dispatch curves associated with operational changes resulting from increased renewables on the Duke Energy system.

Scott Harder stated that SCDNR would like to have the opportunity to see the baseline scenario results before deciding on the minimum increment of significant change (MISC) values.

Dan Rankin indicated the current measures of 10 or 15 consecutive days for black bass spawning are likely too short; the black bass spawning period spans more than 15 days. S. Harder, D. Rankin, and William Wood clarified SCDNR's two main concerns: (1) some performance measure criteria need adjustments and (2) they would like to see the baseline result before setting MISCs.

Alan Stuart asked what SCDNR would like to propose. D. Rankin stated the spawning season criteria would need to be lengthened to realistically capture successful spawning for black bass at Jocassee.

- D. Rankin asked if the baseline would pre-date Bad Creek operations J. Huff responded the model uses historic hydrology and shifts it into the future when it runs operating scenarios. She then described the baseline scenario which incorporates the requirements of the KT license and the upgraded Bad Creek units. The Bad Creek II (BCII) scenario includes the baseline scenario conditions but doubles the number of units at Bad Creek. E. Bruce noted the licensing scenario used for KT relicensing uses a different dispatch curve than what will be used for the Bad Creek relicensing baseline scenario.
- J. Huff asked SCDNR to confirm that for each of the Jocassee black bass spawning measures at different lake level fluctuation bands (-0.5 ft to 2 ft and 3 ft), SCDNR would like to add two measures one for 30 consecutive days and one for 45 consecutive days. She asked the group if there was consensus.
- A. Stuart asked if there would be much difference in the results and the degree of associated effort. J. Huff and E. Bruce responded the computation time would not be greatly increased. D. Rankin asked if there would be benefit in removing the 10, 15, and 20-day criteria and just keeping the 30-and 45-day criteria. Duke Energy and HDR indicated the effort would be the same, so there's no need to remove the 10-, 15-, and 20-day criteria. E. Bruce and A. Stuart asked how SCDNR determined the performance measure consecutive days during the KT relicensing. D. Rankin said he believes it was driven, at least in part, by the U.S. Army Corps of Engineers (USACE) downstream reservoir operations during spawning season.
- E. Bruce indicated Duke Energy would add the new consecutive days and fluctuation criteria; J. Huff agreed and noted Duke Energy and HDR are deferring to stakeholders and those concerned with aquatic resources/fisheries. She also reminded meeting participants the goal is to look at and assess output for Bad Creek II, not baseline output under existing conditions. A. Stuart indicated Duke Energy will go ahead and run for 2 ft and 3 ft fluctuations for 10,15,20,30,45 consecutive days.
- J. Huff asked if SCDNR would like to add the same black bass spawning measures for Lake Keowee as well; D. Rankin responded he didn't think it was necessary based on history in Lake Keowee and spawning success. E. Miller agreed that adding Keowee measures wasn't needed.
- D. Rankin asked if Bad Creek Reservoir was emptied, how much would that raise Lake Jocassee. A. Stuart indicated he thought it was around 4 ft. Kerry McCarney-Castle inserted into the meeting chat per the feasibility report if the total active storage emptied into Lake Jocassee, the lake level would raise 4 ft [Note this is not considering operations at Jocassee].
- J. Huff asked if there were other performance measures the group should discuss.
- E. Miller indicated there were changes they recommended during the July 27th meeting. J. Huff agreed they previously discussed changing the end date for the black bass spawning measure from May 15 to May 31 and also to change the MISC from 10% to 5% for all the spawning period measures. A. Stuart agreed to the conditions and asked if there is value at looking at just the last two

weeks in May on their own. E. Bruce noted that would only make sense if it's connected to the previous period. J. Huff agreed. A. Stuart asked if part of the rationale for choosing May 15 as the end date was based on USACE operations at their downstream project and would there be a concern that since there is already an agreement in place, would we be altering conditions of that agreement. E. Bruce noted production of the performance measures sheet is done in post-processing – nothing about the model scenarios would change.

J. Huff clarified that the performance measures don't affect how the model runs – it's simply a tool for evaluating the model output. In other words, changing the performance measures does not change the model results (i.e., performance measures are not like knobs or levers on a model). The performance measures are there to help assess the output and whether it is favorable. Similar to that, the MISC does not have any bearing on model output, it is simply a visual tool (indicated by different colors) to draw attention to differences between model scenarios (i.e., the MISC does not provide information into the model).

E. Miller asked the group if the end date for the performance measures should be left at May 15 (which is the criteria in the settlement agreement) or should we push it out to May 31; D. Rankin noted that since it's continuous with sunfish spawning it may not matter either way. A. Stuart asked if that is the same for other USACE reservoir periods. D. Rankin was unsure, but noted that in Lake Keowee, spawning is very early (early May) due to warmer waters/thermal discharge from Oconee. Spawning times vary throughout the lake based on temperatures/proximity to the thermal discharge. He also noted that wouldn't be the case in Lake Jocassee (no thermal discharge). D. Rankin said he would defer to E. Miller regarding extension of the spawning criteria end date. J. Huff / E. Bruce noted it wouldn't matter as far as the performance measure production is concerned, so the group agreed to extend the period from May 15 to May 31. SCNDR confirmed they still would like to change the MISC for all the spawning measures to 5% as was proposed at the July meeting.

SCDNR would like to see the baseline scenario output before finalizing the MISCs. The group discussed the granularity of the effort; E. Bruce and J. Huff clarified the difference between baseline and Bad Creek II. A. Stuart stated that a change, for example, from baseline of 5% would be one out of every 20 years. D. Rankin and W. Wood agreed that is minor.

W. Wood reiterated they'd like to see the baseline output before they agree to the MISCs. J. Huff noted that from a scheduling standpoint, this is a challenge. HDR's original plan was to present the modeling results in early October prior to providing the draft study report for stakeholder review. If, however, we need to have a meeting to review the baseline scenario results and revise the MISCs, we likely wouldn't have time to run post-processing of the performance measures sheet and stay on the schedule in the study plan. As an alternative, she suggested run the model and produce the performance measures sheets as planned but can then consider revising MISCs at that point. She reminded the group the only function of the MISC is to draw attention to specific differences between model output. Regardless of the MISC, each performance measure cell would still be populated with the model results for that measure.

- D. Rankin mentioned the SCDNR agreed to the MISCs during KT relicensing (i.e., determined sufficient at that time based on healthy fish population status) so whatever the baseline currently is, that is what the SCDNR originally agreed to; and indicated the concern here is how Bad Creek II affect the fish population.
- J. Huff asked if other stakeholders (other than the SCDNR) would be included in the MISC revisions (since no other comments have been received and SCDNR is the only one that has approached Duke Energy regarding performance measures). Her concern is the amount of time that may be

involved in scheduling a discussion with the larger group. E. Bruce asked what the current schedule is. J. Huff responded we are hoping to have the model output mid-September, review the results with the stakeholders during the first two weeks of October, and then provide the draft report shortly thereafter. Therefore, if additional consultation would be needed (i.e., running baseline, setting MISC, running again), that would push everything out. She suggested again to run the model with the performance measures with the MISCs as-is and potentially modify the MISCs afterwards to eliminate that extra consultation piece. That way, Duke Energy could include all interested stakeholders (not just the SCDNR) in the meeting to go over results and provide the opportunity to view output with MISCs.

A. Stuart noted that would be ok in terms of process, but his concern is the schedule and HDR modeler's medical leave and indicated we could just go with the MISCs that we have and revise after results are provided. If SCDNR doesn't want to see Bad Creek II output, that can be held back.

E. Bruce asked for clarification if SCDNR is ok with the MISCs for the non-fish related measures (such as drought conditions). E. Miller indicated things like that would be out of anybody's control and noted that other MISCs are fine. E. Miller mentioned there could be some potential for other (recreation) people to want to revise the MISCS, also noting everybody is in agreement that the schedule is important. If Duke Energy/HDR can review model output with SCDNR late September, the meeting to go over everything with the RC could be held in early October before HDR modeler's medical leave. If MISCs are revised at that point, Duke Energy would need to re-run the performance measures sheets; Duke Energy and HDR are committed to thorough documentation of the process along the way, especially to capture changes between the draft CHEOPS (Task 4) report and the final (following RC meeting).

A. Stuart reiterated that the consensus is to produce the performance measures sheets using the 5% MISC for fish spawning measures and May 31 extension of the spawning period measures.

E. Bruce asked if B. Krolak (HDR) could be a back-up modeler. J. Huff indicated he or another person in HDR could be possible stand-ins for modeling if schedule became a problem.

Action Items

- The meeting recording and meeting summary will be posted to the Resource Committee SharePoint site and the link will be distributed.
- The consensus from today's meeting is to proceed with running the CHEOPS model (baseline and Bad Creek II) and producing the performance measures sheet for presentation in early October meeting with stakeholders.
- Performance measure changes include the following: include Jocassee black bass spawning measures to evaluate consecutive days criteria for spawning by adding 30 and 45 days.
- Model to run with modifications suggested during the July 27th joint RC meeting to extend spawning performance measure criteria from May 15 to May 31 and decrease the MISC from 10% to 5%.

Subject: Bad Creek Relicensing Water Resources Committee - Summary of Existing Water Quality Data and Standards Draft Report (Ready for Resource Committee Review)

Importance: High

Dear Bad Creek Relicensing Water Resources Committee:

Duke Energy is pleased to distribute the draft report <u>Summary of Existing Water Quality Data and Standards</u> for Resource Committee review. This draft report satisfies Task 1 of the Bad Creek Relicensing Water Resources Study. The deliverable and associated appendices are available on the Bad Creek Relicensing SharePoint site at the following link: <u>Water Resources Study Reports for RC Review</u>. Duke Energy is requesting a 60-day review period, therefore, please submit all comments by **August 29th**. A confirmation email is kindly requested upon review completion (<u>John.Crutchfield@dukeenergy.com</u>).

Important - Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document. This will eliminate version control issues and result in a consolidated document for comment response.
- We **strongly recommend** opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (circled in red on the screenshot below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to Maggie Salazar for SharePoint access assistance or questions.
- If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page (green bar) of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. (Note the tutorial provides an alternative way to open the document in Word either technique works!)
- Finally, please note the report appendices are provided in the folder as a PDF. There is no way to comment on a PDF from SharePoint; therefore, we suggest either making the comment in the Word document with reference to the figure/page number or providing figure comments in a separate email

Please let Alan Stuart or me know if you have any questions.

Thank you,

John Crutchfield

My apologies for missing this deadline. Is it now too late to comment?

This is what Dr. Hains just submitted to me:

After review, the hydrodynamic modeling regarding the submerged weir and the interactions of proposed changes in operation resulting from pumped-storage expansion - seems thorough and state-of-art. I am satisfied with both my ability to understand and interpret the model predictions as well as the validity of the predictions. I see no reason to object to expansion of the submerged weir. Overall I think the hydrodynamic model effort is satisfactory, perhaps even exemplary. That said, it will be interesting to observe future trends of the heat budget for Lake Jocassee and changes, if any, in response to the operational changes.

After review of the CHEOPS model presentation, I wish I could be as confident with that effort as I am with the hydrodynamic modeling. However, there are so many factors under consideration for CHEOPS that it is difficult to arrive at an independent assessment. I am not sure my background is adequate for such an assessment and at this time, any further comment I have might merely serve to confuse things. Therefore I opt not to comment one way or the other.

Subject: Bad Creek Relicensing - Task 2 CFD Modeling Report for Resource Committee Distribution and Review

Importance: High

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Duke Energy is pleased to distribute the draft report <u>Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse</u> (i.e., CFD Modeling Report) for Resource Committee review. This draft report satisfies Task 3 of the Bad Creek Relicensing Water Resources Study. The deliverable and associated appendix are available on the Bad Creek Relicensing SharePoint site at the following link: <u>Task 3 - Velocity Effects & Vertical Mixing In Lake Jocassee (CFD Modeling Report)</u>. Duke Energy is requesting a 30-day review period, therefore, <u>please submit all comments by October 11th</u>. A confirmation email is kindly requested upon review completion (<u>John.Crutchfield@duke-energy.com</u>).

<u>Important – Please Read!</u>

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables
 available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore,
 we request all comments be made in the SharePoint Word document. This will eliminate version control issues
 and result in a consolidated document for comment response.
- We <u>strongly recommend</u> opening the document in Word; otherwise the formatting will look distorted. The
 simplest way to do this is to click on the three dots to the right of the document (shown below), choose "Open",
 then choose "Open in app". This will open the document in Word and you'll have the functionality you are
 accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to <u>Maggie</u>
 Salazar for SharePoint access assistance or questions.

- If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page (green bar) of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. (Note the tutorial provides an alternative way to open the document in Word either technique works!)
- Finally, please note the report appendix (Appendix A) is provided in the folder as a PDF. There is no way to comment on a PDF from SharePoint; therefore, we suggest either making the comment in the Word document with reference to the figure/page number or providing figure comments in a separate email.

Please let me know if you have any questions.

Regards,

John Crutchfield

Subject: Bad Creek Relicensing Water Resources Committee - Summary of Existing Water Quality Data and Standards

FINAL Report Importance: High

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Water Resources Committee:

The <u>Summary of Existing Water Quality and Data Standards Final Report</u> is available on SharePoint (.pdf file, SharePoint link provided below). For those who submitted comments, the comments and edits have been addressed in the final report and Duke Energy's responses are captured in a brief comment response table (SharePoint Link also provided below).

Bad Creek Relicensing Summary of Existing Water Quality Data and Standards Final Report 20230912.pdf

Stakeholder Comment Response Table.pdf

Duke Energy plans to file the final report with the next quarterly progress report due to FERC by end of September.

Please let Alan or me know if you have any questions.

Thank you,

John Crutchfield

Agency	Date Submitted	Report Section	Comment	Duke Energy Response
USFWS	7/26/2023		No comments.	No response needed.
Upstate Forever	8/21/2023	5.3.1	This is statement is confusing. How can the samples meet state standards without a numeric threshold? The comment is regarding the following sentence: There is no numeric threshold, however, for trout waters, state standards dictate water temperatures should not vary from levels existing under natural conditions (unless determined some other temperature shall protect the classified uses). Were all samples surface water samples?	South Carolina state water quality standards are used as instream water quality goals to maintain and improve water quality and also serve as the foundation of the Bureau of Water's program. A site-specific numeric standard may be established by the Department; however, some criteria are narrative criteria that describe the desired water quality goal. Narrative criteria provide additional protections when numeric criteria are difficult to specify. The state standard for temperature for trout waters in South Carolina is: Not to vary from levels existing under natural conditions, unless determined some other temperature shall protect the classified uses. Based on Duke Energy's assessment of historic water quality data, the narrative criteria is considered to be met. Minor edits to the report have been incorporated to clarify this point. Yes, all dissolved oxygen (DO) field measurements included in this evaluation were made at the surface (as defined by 0.3-meter-depth per SCDHEC assessment methodology). The word "surface" was added to the sentence to provide added clarification.
		5.3.2, Table 5-5	Provide explanation of below the table.	Per page 70 of 234 of the appendices, DO saturation was not monitored at Station 565.4. The () was meant to indicate "No Data". Clarification has been added as a table note.
		5.3.5	Fix spacing so the table fits on one page	Formatting adjustment made.
		5.3.8	Prefer if entire table was on same page if possible.	Formatting adjustment made.
		5.3.8	Which standard? I'm assuming freshwaters (25 NTU)?	Because Lake Jocassee uses a state standard of 10 NTU for trout waters as described in Section 5.3.8, the sentence refers to the state standard of 10 NTU. Clarification to the sentence was made.

Agency	Date Submitted	Report Section	Comment	Duke Energy Response
Friends of Lake Keowee Society (FOLKS)	7/9/2023	N/A	The report was very thorough and detailed the findings of pre- and post construction to the Bad Creek pump station. The data illustrated that there was little if any pre- to post differences in the studied parameters. FOLKS's primary concern still rests in the area of Howard Creek, which is a high value recreational fishing stream and vital to trout habitat. We are confident that Duke Energy will continue to study future impacts should Bad Creek II pumpstation move forward and will mitigate as necessary to preserve the quality of that creek.	No response needed.
		5.1	Change "ft" to "foot"	Edit accepted.
		5.2	Change "provide" to "provided"	Edit accepted.
		5.3.2, Table 5-5	Can you address why this data is missing?	Per page 70 of 234 of the appendices, DO saturation was not monitored at Station 565.4. The () was meant to indicate "No Data". Clarification has been added as a table note.
		5.3.7	Consider eliminating the word "fairly".	Edit accepted.
		5.3.8	No comma needed between month and yearsame for next bullet	Edit accepted.
		5.3.8	Add comma after year	Edit accepted.
		10	Delete comma.	Edit accepted.
Advocates for Quality Development	8/29/203	NA	No comments.	No response needed.

Hi John,

The SCDNR has reviewed the meeting summary and Performance Measures spreadsheet. The SCDNR notes that measures 11 and 12 should be corrected to reflect the 2.5-ft fluctuation band and be described as within -0.5 to 2.0 ft. Similarly, measures 16 and 17 should be corrected to reflect the 3.0-ft fluctuation band and described as within -0.5 to 3.0 ft. Please let me know if you have any questions.

Thank you,

Elizabeth

John,

The Service has completed review of the CFD Modeling Report. I don't have any comments and will defer to other agencies that have more specialized experience in this type of modeling.

This email has been received from outside of DOI - Use caution before clicking on links, opening attachments, or responding.

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Duke Energy is pleased to distribute the draft report <u>Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse</u> (i.e., CFD Modeling Report) for Resource Committee review. This draft report satisfies Task 3 of the Bad Creek Relicensing Water Resources Study. The deliverable and associated appendix are available on the Bad Creek Relicensing SharePoint site at the following link: Task 3 - Velocity Effects & Vertical Mixing In Lake Jocassee (CFD Modeling Report). Duke Energy is requesting a 30-day review period, therefore, please submit all comments by October 11th. A confirmation email is kindly requested upon review completion (John.Crutchfield@dukeenergy.com).

Important - Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document. This will eliminate version control issues and result in a consolidated document for comment response.
- We **strongly recommend** opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (shown below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to **Maggie Salazar** for SharePoint access assistance or questions.
- If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page (green bar) of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. (Note the tutorial provides an alternative way to open the document in Word either technique works!)
- Finally, please note the report appendix (Appendix A) is provided in the folder as a PDF. There is no way to comment on a PDF from SharePoint; therefore, we suggest either making the comment in the Word document with reference to the figure/page number or providing figure comments in a separate email.

Please let me know if you have any questions.

Regards,

John Crutchfield

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Duke Energy is pleased to distribute the draft report <u>Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse</u> (i.e., CFD Modeling Report) for Resource Committee review. This draft report satisfies Task 3 of the Bad Creek Relicensing Water Resources Study. The deliverable and associated appendix are available on the Bad Creek Relicensing SharePoint site at the following link: Task 3 - Velocity Effects & Vertical Mixing In Lake Jocassee (CFD Modeling Report). Duke Energy is requesting a 30-day review period, therefore, please submit all comments by October 11th. A confirmation email is kindly requested upon review completion (John.Crutchfield@dukeenergy.com).

Important - Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document. This will eliminate version control issues and result in a consolidated document for comment response.
- We <u>strongly recommend</u> opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (shown below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to <u>Maggie Salazar</u> for SharePoint access assistance or questions.
- If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page (green bar) of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. (Note the tutorial provides an alternative way to open the document in Word either technique works!)
- Finally, please note the report appendix (Appendix A) is provided in the folder as a PDF. There is no way to comment on a PDF from SharePoint; therefore, we suggest either making the comment in the Word document with reference to the figure/page number or providing figure comments in a separate email.

Please let me know if you have any questions.

Subject: Bad Creek Relicensing - Task 2 CFD Modeling Report for Resource Committee Distribution and Review

Importance: High

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Duke Energy is pleased to distribute the draft report <u>Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse</u> (i.e., CFD Modeling Report) for Resource Committee review. This draft report satisfies Task 3 of the Bad Creek Relicensing Water Resources Study. The deliverable and associated appendix are available on the Bad Creek Relicensing SharePoint site at the following link: <u>Task 3 - Velocity Effects & Vertical Mixing In Lake Jocassee</u> (CFD Modeling Report). Duke Energy is requesting a 30-day review period, therefore, <u>please submit all comments by October 11th</u>. A confirmation email is kindly requested upon review completion (<u>John.Crutchfield@dukeenergy.com</u>).

Important - Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document. This will eliminate version control issues and result in a consolidated document for comment response.
- We **strongly recommend** opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (shown below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to **Maggie Salazar** for SharePoint access assistance or questions.
- If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page (green bar) of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. (Note the tutorial provides an alternative way to open the document in Word either technique works!)
- Finally, please note the report appendix (Appendix A) is provided in the folder as a PDF. There is no way to comment on a PDF from SharePoint; therefore, we suggest either making the comment in the Word document with reference to the figure/page number or providing figure comments in a separate email.

Subject: Bad Creek Relicensing - CFD Modeling FINAL Report Posted on Stakeholder SharePoint Site

Date: Friday, October 27, 2023 9:35:02 AM

Attachments: <u>image001.png</u>

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Good morning!

The final CFD modeling report "Velocity Effects and Vertical Mixing in Lake Jocassee due to a Second Powerhouse" (Task 3 of the Water Resources Study) is available on SharePoint at the link below. This report will be filed with the Initial Study Report in January. We appreciate feedback received on the report - a brief comment response table is also provided at the SharePoint link and includes Duke Energy's responses to comments.

Final Report

Thank you for your participation in the Bad Creek relicensing and we look forward to continued collaboration in the coming months.

Regards,

John Crutchfield

Agency	Date Submitted	Comment	Duke Energy Response
USFWS	9/27/2023	No comments.	No response needed.
AQD	10/5/2023	No comments.	No response needed.
Friends of Lake Keowee Society (FOLKS)	ee 10/11/2023	I have read the CFD document and in my opinion the technical approach to the modeling study is sound. I have no criticisms to what has been done or what was described in the document. However, I do have some additional comments and questions that relate, I believe, to aspects of the limnology of this system that may not be addressed by this effort. Please correct me if I am mistaken or if these aspects are going to be addressed in other phases of these studies.	Thank you for your review. Duke Energy appreciates your feedback conveying your approval of the CFD modeling approach and results covered under Task 3 of the Bad Creek Water Resources Study for Project relicensing. The main objective of this study task was to develop 2-D and 3-D models and use these models to evaluate flows and the extent of vertical mixing in the Whitewater River cove (downstream of the submerged weir) due to the addition of a second inlet/outlet structure. Key results indicate hydraulic effects in Lake Jocasee due to operations are limited to the area upstream of the Devil's Fork / Whitewater River confluence and natural stratification is maintained downstream of the weir under all modeled scenarios. Model results show Bad Creek II powerhouse operations will not alter existing stratification patterns observed downstream of the weir or further downstream into Lake Jocassee. Some aspects of biological, chemical, and physical features of Lake Jocassee (i.e., limnology) are incorporated in part under other studies, namely Tasks 2 and 3 of the Aquatic Resources Study (i.e., biology and aquatic habitat), Task 1 of the Water Quality Study (i.e., historic and current water quality trends including
		1. The mean discharge of the Savannah River at Clyo, GA is in the range of 9K cfs. The maximum outflow that has been projected for Bad Creek under the operation of the additional powerhouse is therefore about three times the mean flow of the Savannah River near its mouth for whatever length of time that power demand requires such release from Bad Creek. That, to my mind, raises a few questions that appear not to be addressed by the modeling effort.	stratification), and Task 5 (future Water Quality Monitoring Plan); however, based on FERC project nexus and the seven study criterial, other aspects, including movement of water through the watershed and biogeochemical changes that occur en route, aren't considered to be affected by Bad Creek Project operations and, therefore, were not included in FERC's Study Plan Determination. The total contributing drainage area for the Bad Creek Reservoir is approximately 1.5 square miles (mi²), therefore, downstream contributing flows are minor (approximately 5.0 cubic feet per second from seepage through the dams). Water is exchanged between the upper Bad Creek Reservoir and Lake Jocassee, commonly alternating between generating and pumping on a daily basis; the maximum allowable drawdown is 160 feet, which will not change under the proposed configuration. Flows exchanged between the two water bodies do not directly connect with flows in the Savannah River, therefore there is no impact on flows downstream in the Savannah River resulting from Bad Creek Project operations. The exception would be during extreme droughts where Duke Energy must release Bad Creek's storage to stay in compliance with USACE and SEPA to maintain hydropower generating requirements downstream. Additionally, there are 8 dams downstream of Bad Creek and accounting for attenuation over more than 300 miles of stream length as well as reservoir retention/evaporation downstream, plus various water uses downstream along the water course, one would not expect similarity in a direct comparison of Bad Creek Project flows with flows near the mouth of the Savannah River.
		2. There is a well-established concept that has to do with vertical transport of thermal energy (heat) during wind-induced water movement, called 'work of the wind'. In this process a lake that experiences wind-forced lateral shear currents and resulting eddy diffusivity tends to transport energy (primarily, but not limited to, absorbed solar energy) to depths greater than expected without such water motion. While wind may not be a great factor for such transport to great depths in Lake Jocassee compared to pumped-storage operation at Jocassee Hydro, flows such as predicted by this document (3x the Savannah River) may induce such transport and thus affect the lake in a similar manner. The question therefore remains as to how much such transport will occur and what will be its lateral and vertical extent into Lake Jocassee as well as its resulting effect on vertical thermal patterns.	Heat transport due to wind was not included in the scope for Task 3 (i.e., CFD modeling of the Whitewater River arm to determine velocity and mixing effects downstream of the submerged weir due to a second powerhouse). It is important to remember that Bad Creek is a pumped storage system, such that water is exchanged between the upper and lower reservoirs; the water is not altered in any way and the retention time in the upper reservoir is very short due to frequent exchange. This will also be true of Bad Creek II; the same volume of water will be exchanged between the two reservoirs, albeit more frequently. CFD modeling indicates that vertical mixing from Project flows is limited to the portion of Whitewater River arm upstream of the weir (under both Project scenarios). Based on historical and current water quality data at depth, vertical temperature and DO stratification is observed across all water quality monitoring sites in Lake Jocassee. Wind-induced water movement and subsequent transport of thermal energy during wind-induced water movement is a natural process not impacted by the existing or proposed projects, nor is there a connection between the project and its potential effect on the applicable resource, and therefore, would not meet FERC relicensing nexus criteria. [§5.9(b)(5) Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.]
		3. Given this unknown, and building on the aforementioned question, it would be a useful (and feasible) exercise to compute both the empirical (Birgean) and the analytical heat budgets for all years prior to and after the operation of the Bad Creek Project. For past years the two approaches would allow for a comparison and measure of their accuracy. Then, employing the capability of the hydrodynamic model, to predict the heat budgets for Lake Jocassee that result during max/min operations conditions for the additional units in Bad Creek II.	Computation of heat budgets for Lake Jocassee was not included in the scope for Task 3 (i.e., CFD modeling of the Whitewater River arm to determine velocity and mixing effects downstream of the submerged weir due to a second powerhouse). The heat budget of a reservoir is typically controlled by heat fluxes at the lake surface including shortwave radiation, incoming and outgoing longwave radiation, and the latent heat flux. ² These are natural processes and not impacted by the existing or proposed projects, nor is there a connection between the project and its potential effect on the applicable resource, and therefore, would not meet FERC relicensing nexus criteria. [\$5.9(b)(5) Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.]

Agency	Date Submitted	Comment	Duke Energy Response
		4. Aspects such as these will be quite different between stratified and non-stratified conditions and may find the greatest sensitivity for operation during a transition period such as occurs during spring warming. It would be important to address this for all months and all operational conditions such as lake surface elevation and release dynamics.	Historical water quality monitoring data show most years exhibit year-round stratification at all monitoring stations in Lake Jocassee except for the station immediately downstream of the Project discharge where water is mixed. All seasons have been evaluated for stratification patterns (DO and temperature) in Lake Jocassee and the period of record (40 plus years) shows stratification is maintained throughout all seasons, with the exception of very cold winters when the lake becomes isothermal, though at varying depths depending on season. CFD modeling results (and historical water quality data) show stratification downstream of the submerged weir is retained, including scenarios of Bad Creek I and Bad Creek II operating under maximum drawdown conditions (1,080 feet above mean sea level). Additionally, because Bad Creek operates as a pumped storage, there are no additive effects on thermal characteristics or aquatic habitat in the lake and no concern for thermal alteration on biological processes. Additionally, release dynamics are not applicable to the existing (or proposed) project operations. Under existing license articles for the Project as well as the Memorandum of Understanding (MOU) between Duke Energy and the South Carolina Department of Natural Resources, long-term monitoring of trout habitat and water quality will continue to ensure management and maintenance of the high-quality fishery resources.
		5. In other studies of pumped-storage, the supplemental kinetic energy during operations has been found to stimulate biological processes such as primary production. Because the nature of such stimulation is dependent on the unique characteristics of each situation this may or may not be of importance for Lake Jocassee. The potential influence of thermal alterations on biological processes merely adds an additional 'layer' to the question. This question may fall outside of the scope of the CFD modeling effort. Nevertheless, it is an unknown that needs to be addressed during some aspect of this overall study effort for relicensing and the addition of Bad Creek II.	The supplemental kinetic energy created during project operations has not been evaluated, nor its potential to stimulate biological processes (water from the upper reservoir is released in generating mode, converting from potential energy to kinetic energy by the flowing water). Water quality and biological/aquatic monitoring has been performed since the impoundment of the reservoir. Lake Jocassee is designated as TPGT, which are freshwaters suitable for supporting growth of stocked trout populations and a balanced indigenous aquatic community of fauna and flora. Lake Jocassee is included in the highest water quality classification (i.e., excellent rating) as designated by SCDHEC and preservation of existing conditions is recommended, with most tributaries within the watershed fully supporting their designated use. Lake Jocassee is one of only a few reservoirs in South Carolina that possesses the necessary aquatic habitat (water temperatures and DO) to support both a warmwater and a coldwater (salmonid [trout]) fishery year-round. SCDHEC has consistently identified Lake Jocassee (as well as downstream Lake Keowee) among the cleanest South Carolina reservoirs based on data from 1980-1981, 1985-1986, and 1989-1990 studies. Recent data continue to indicate Lake Jocassee fully supports aquatic life and recreational designated uses under current Project operations and this is expected to remain the same under future operations (i.e., with the addition of Bad Creek II) given the CFD model results which indicate limited, rapidly dissipating mixing on the downstream side of the submerged weir. Therefore, supplemental energy from the existing (or proposed) powerhouse is not

anticipated to alter or stimulate biological processes in the lake.

Subject: Bad Creek Relicensing - ILP Study Plans and Reports Schedule Update

Date: Tuesday, October 31, 2023 12:02:43 PM

Importance: High

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

I hope this email finds you well and that you have been able to get out and enjoy the fantastic weather we are having this fall. It is hard to believe it is nearly November, and as we all know, the days start slipping by quickly as the year wraps up.

Duke Energy and our consultants have been working diligently to complete the first year ILP studies and advance the study reports. I wanted to take this opportunity to provide you with a preview of Resource Committee reviews that will be requested over the next month and the upcoming FERC ILP process milestones.

- 1. **Initial Study Report (ISR)** We expect to file the ISR on or just before the FERC ILP deadline of January 4, 2024.
- 2. ISR Meeting The ISR meeting is to be held within 15 days of the ISR filing. Duke Energy is coordinating availability with FERC staff, and we are presently planning to conduct the ISR Meeting at the Duke Energy Wenwood Operations Center (Greenville, SC) on Wednesday, January 17th. Please note this meeting date is subject to change depending up FERC staff availability and if it shifts to another date in January, we will let you know so you can plan accordingly. Your attendance at this meeting is greatly appreciated and encouraged, but a Teams meeting will be made available for participants who are unable to travel.

3. Water Resources Study Reports

- a. **Task 2** study report "Whitewater River Cove Water Quality Field Study":
 - i. Will not be completed until the end of the 2024 (2nd) ILP study season.
 - ii. A summary of Year 1 results will be provided in the ISR.
- b. **Task 3** study report "Velocity Effects and Vertical Mixing in

Lake Jocassee Due to a Second Powerhouse":

- i. The Resource Committee comment period on this report is closed.

 Thank you to RC members who provided comments.
- ii. We are developing an addendum to that report to include field verification results (ADCP velocity measurements in the Whitewater River Cove) as discussed at the July 27th Joint RC Meeting. This addendum will be submitted to the Water Resources RC (via the SharePoint Site) by November 10 for a 30-day review and will be submitted with the ISR.
- iii. The Task 3 study report (in entirety) will be filed with FERC with the ISR. This filing will include documentation of consultation with the RC and response to comments received. (Responses to comments will also be posted separately to the SharePoint site).
- c. **Task 4** study report "Water Exchange Rates and Lake Jocassee Reservoir Levels":
 - The Duke Energy relicensing team continues to work through CHEOPS model updates, calibration, and simulations of the designated operating scenarios for Bad Creek II. We presently expect to include a status update in the ISR and distribute the draft report to the Water and Aquatics Resources RCs in Q1 2024.

4. Aquatic Resources Study Reports

- a. **Task 1** study report "Entrainment Report (Revised)" will be shared with the Aquatics RC by November 3 for a final 30-day review period.
- b. **Task 2** study report "Desktop Studies on Pelagic and Littoral Habitat Effects" requires input from the Water Resources Task 4 study report described above. We presently expect to include a status update in the ISR and distribute the draft report to the Aquatics RC in Q1 2024.
- c. **Task 3** study report "Mussel Surveys and Stream Habitat Quality Surveys" will be submitted to the Aquatics RC as a draft for review and we are targeting submittal to the RC by November 17. Duke Energy will be requesting an expedited (3-week) review period by the RC, due to the coming holidays.

If you have any questions at all about any of the activities described above or the process in general, please do not hesitate to reach out to me or Alan Stuart directly.

Thank you for your continued participation in this process, and on behalf of Duke Energy, we look forward to a productive quarter and advancing the Bad Creek Project relicensing in collaboration with this group and other stakeholders.

Regards,

John Crutchfield

Subject: Bad Creek Relicensing - CFD Verification Addendum Report Review Request

Date: Monday, November 6, 2023 10:39:41 AM

Attachments: image001.png image002.png
Importance: High

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Duke Energy is pleased to distribute the <u>Bad Creek CFD Model Verification Draft Addendum</u> for stakeholder review. This draft report includes methods and results of the field study performed to verify CFD modeling results and will be attached to the already-finalized Task 3 study report (Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse). The deliverable is available on the Bad Creek Relicensing SharePoint site at the following link: CFD Model Verification Addendum Draft Report.

Duke Energy is requesting a 30-day review period, therefore, please submit all comments by **<u>December 6th</u>**. A confirmation email is kindly requested upon review completion (email me at <u>John.Crutchfield@duke-energy.com</u>).

Important – Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document using tracked changes. This will eliminate version control issues and result in a consolidated document for comment response.
- We strongly recommend opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (example shown below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word — either technique works!])

If you have any questions, please contact Alan Stuart or me.

Subject: RE: Bad Creek Relicensing - CFD Verification Addendum Report Review Request

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Just a reminder comments are due on the Bad Creek CFD Model Verification Draft Addendum by **December 6th**.

Regards,

John Crutchfield

From: Crutchfield Jr., John U

Sent: Monday, November 6, 2023 10:39 AM

Subject: Bad Creek Relicensing - CFD Verification Addendum Report Review Request

Importance: High

Dear Bad Creek Relicensing Water and Aquatic Resources Committees:

Duke Energy is pleased to distribute the <u>Bad Creek CFD Model Verification Draft Addendum</u> for stakeholder review. This draft report includes methods and results of the field study performed to verify CFD modeling results and will be attached to the already-finalized Task 3 study report (Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse). The deliverable is available on the Bad Creek Relicensing SharePoint site at the following link: <u>CFD Model Verification Addendum</u> <u>Draft Report</u>.

Duke Energy is requesting a 30-day review period, therefore, please submit all comments by **December 6th**. A confirmation email is kindly requested upon review completion (email me at John.Crutchfield@duke-energy.com).

Important – Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document using tracked changes. This will eliminate version control issues and result in a consolidated document for comment response.
- We strongly recommend opening the document in Word; otherwise the formatting will look distorted. The
 simplest way to do this is to click on the three dots to the right of the document (example shown below),
 choose "Open", then choose "Open in app". This will open the document in Word and you'll have the
 functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free
 to reach out to @McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word – either technique works!])

If you have any questions, please contact Alan Stuart or me.

Regards,

John Crutchfield

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Resource Committee members:

Duke Energy is pleased to distribute the draft Water Resources – Task 4 (i.e., CHEOPS Modeling) report for your review. This draft includes the results from CHEOPS modeling for the Baseline and Bad Creek II scenarios as well as populated Performance Measures sheets. The draft report is available on the SharePoint site using this link: Bad Creek Relicensing Project — Resource Committees - Draft CHEOPS report - All Documents (sharepoint.com).

Please provide your comments within the draft report using Track Changes as explained further below within 30 days (**April 26, 2024**). When you have completed your review – even if you have no comments – I would appreciate an email stating that is the case.

Important - Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy is providing relicensing deliverables on the SharePoint site for relicensing participants to access, review, and comment on files. Please <u>provide all</u> <u>comments in the SharePoint Word document using tracked changes</u>. This will eliminate version control issues, enable relicensing participants to gain insight into one another's comments, and result in a consolidated document for comment response.
- We strongly recommend opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (example shown below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Subject: Bad Creek Relicensing - CHEOPS Modeling Draft Report Ready for Review and April 4 Meeting Agenda

Dear Bad Creek Resource Committee members:

Duke Energy is pleased to distribute the draft Water Resources – Task 4 (i.e., CHEOPS Modeling) report for your review. This draft includes the results from CHEOPS modeling for the Baseline and Bad Creek II scenarios as well as populated Performance Measures sheets. The draft report is available on the SharePoint site using this link: Bad Creek Relicensing Project – Resource Committees - Draft CHEOPS report - All Documents (sharepoint.com).

Please provide your comments within the draft report using Track Changes as explained further below within 30 days (**April 26, 2024**). When you have completed your review – even if you have no comments – I would appreciate an email stating that is the case.

Important - Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy is providing relicensing deliverables on the
 SharePoint site for relicensing participants to access, review, and comment on files. Please <u>provide all</u>
 comments in the SharePoint Word document using tracked changes. This will eliminate version control issues,
 enable relicensing participants to gain insight into one another's comments, and result in a consolidated
 document for comment response.
- We strongly recommend opening the document in Word; otherwise the formatting will look distorted. The
 simplest way to do this is to click on the three dots to the right of the document (example shown below),
 choose "Open", then choose "Open in app". This will open the document in Word and you'll have the
 functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free
 to reach out to McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word — either technique works!])

We will be discussing the draft report and report findings during the April 4, 2024, Joint Resource Committee meeting. I have attached the meeting agenda for your reference.

If you have questions, please contact Alan Stuart or me.

Subject: Bad Creek Relicensing - CHEOPS Modeling Draft Report Ready for Review and April 4 Meeting Agenda

Dear Bad Creek Resource Committee members:

Duke Energy is pleased to distribute the draft Water Resources – Task 4 (i.e., CHEOPS Modeling) report for your review. This draft includes the results from CHEOPS modeling for the Baseline and Bad Creek II scenarios as well as populated Performance Measures sheets. The draft report is available on the SharePoint site using this link: Bad Creek Relicensing Project – Resource Committees - Draft CHEOPS report - All Documents (sharepoint.com).

Please provide your comments within the draft report using Track Changes as explained further below within 30 days (**April 26, 2024**). When you have completed your review – even if you have no comments – I would appreciate an email stating that is the case.

<u>Important – Please Read!</u>

1. As discussed in the kick-off meeting (July 2022), Duke Energy is providing relicensing deliverables on the SharePoint site for relicensing participants to access, review, and comment on files. Please provide all comments in the SharePoint Word document using tracked changes. This will eliminate version control issues, enable relicensing participants to gain insight into one another's comments, and result in a consolidated document for comment response.

2. We strongly recommend opening the document in Word; otherwise the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (example shown below), choose "Open", then choose "Open in app". This will open the document in Word and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to @McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word – either technique works!])

Meeting Minutes

Project:	Bad Creek Relicensing
Subject:	CHEOPS Results and CFD Addendum
Date:	Thursday, April 04, 2024
Location:	Teams

Attendees:

Sue Williams (AQD)
Gerry Yantis (AQD)
John Crutchfield (Duke Energy)
Lynne Dunne (Duke Energy)
Alan Stuart (Duke Energy)
Glenn Hilliard (FTC)
John Hains (FOLKS)
Dale Wilde (FOLKS)
Jen Huff (HDR)

Sarah Kulpa (HDR)
Kerry McCarney-Castle (HDR)
Angie Scangas (HDR)
Ty Ziegler (HDR)
Wes Cooler (Naturaland Trust)
Morgan Amedee (SCDHEC)
Amy Chastain (SCDNR)
Elizabeth Miller (SCNDR)
Rowdy Harris (SCDPRT)

Introduction

John Crutchfield opened the meeting, facilitated introductions, shared the agenda, and provided a safety moment on safe driving through work zones.

CHEOPS Modeling Discussion

Jen Huff provided opening remarks for the CHEOPS discussion, noting that HDR's lead modeler Angie Scangas has limited connectivity (due to snowstorm in New England) so J. Huff will cover the presentation, but A. Scangas will be available to answer technical questions. J. Huff then presented a refresher on the CHEOPS model and the Savannah River CHEOPS model developed for Keowee-Toxaway Project (KT) relicensing. The Savannah River CHEOPS model includes the 2014 Operating Agreement between Duke Energy, U.S. Army Corps of Engineers (USACE), and Southeastern Power Administration (SEPA) as well as the requirements of the KT Low Inflow Protocol (LIP).

Adjustments to the Savannah River model for Bad Creek relicensing included updating the generation and pumping load shapes for Bad Creek Pumped Storage Station (Bad Creek) and Jocassee Pumped Storage Station (Jocassee). J. Huff presented a graph for an example day (July 6, 2011) with the original pump/gen cycle used during KT relicensing and the updated pump/gen cycle used for Bad Creek relicensing (Slide 9). During KT relicensing, Bad Creek and Jocassee typically generated during the day and pumped at night. Now, however, increased renewables on the Duke Energy system cause pumping during the afternoon with generation needed at night. Generating and pumping is also influenced by how much water is available and FERC license requirements.

No changes were made to the hydrology dataset which includes 1939 - 2011 daily unimpaired inflow (UIF) hydrology. Operations under two climate change conditions were also modeled: (1) CCLow represents a 3°F temperature increase (with 10% increase in evaporation) and (2) CCHigh represents a 6°F degree temperature increase (with 20% increase in evaporation) plus 10% decrease in inflow to the system.

The two model scenarios were: (1) Baseline (existing facilities and FERC license requirements) and (2) Baseline + Bad Creek II (i.e., the alternative).

J. Huff explained under typical operations, Bad Creek and Jocassee operate together in sync (i.e., when one pumps, the other pumps, and when one generates, the other generates). Therefore, the Bad Creek and Jocassee reservoir elevations have generally risen and fallen in tandem as demonstrated on Slide 12 by the green "reservoir elevation line" on the Baseline scenario figures. Under the Bad Creek II scenario, Bad Creek pumps more water to the Upper Reservoir (UR) and exceeds the amount Jocassee pumps from Lake Keowee for a period of time (the negative inflow period shown on the graph). This causes the green reservoir elevation line for Jocassee to remain in a smaller "band". Ty Ziegler added that the increase in generation and pumping capability with Bad Creek II will have a more dramatic effect on UR elevations and less of an effect on the lower reservoir (Lake Jocassee elevation).

Dale Wilde asked if the green line (elevation) on the upper right figure (Slide 12) goes down to 30,000. J. Huff explained the green line is aligned with the right-hand axis (elevation in feet). A. Scangas added that hydroelectric operations (blue line) correlates to the left-hand axis (flow in cubic feet per second). T. Ziegler noted that with Bad Creek II the hydraulic capacity is essentially doubled so the UR will be better utilized with Bad Creek II operations; only a portion of the capacity of the UR is currently used. Accordingly, the model shows more water fluctuation in the UR and less fluctuation in Lake Jocassee under the Bad Creek II scenario. Approximately 0.5 feet less fluctuation occurs at Jocassee under the Bad Creek II scenario.

J. Huff showed simulated reservoir elevations for Bad Creek under Baseline and Bad Creek II under climate change scenarios, noting that under CCHigh conditions, the model simulated Bad Creek reservoir near maximum drawdown at times. However, during these times pumping and generating was still simulated as water moves within the Duke Energy system.

Glenn Hilliard asked if there could be a situation in the future with extreme (high) temperatures and full use of Bad Creek II, where there is a risk for power production problems such that power may not be available on subsequent days and Duke Energy would not be able to operate. J. Huff noted that the 2014 Operating Agreement dictates how much water can be used/stored in Duke Energy reservoirs during times of low-inflow periods (i.e., droughts) versus the downstream USACE reservoirs. Duke Energy cannot stop releases from Keowee such that lower reservoirs (downstream) don't have enough water to continue releases into the Savannah River. The 2014 Operating Agreement ensures that the amount of usable storage in the system remains in balance. A specified volume of water can be kept in the upper reservoirs during severe drought conditions.

T. Ziegler added that the 73-year hydrology dataset used for CHEOPS captures the most severe drought that has occurred in the basin.

J. Huff discussed Lake Jocassee reservoir elevations, showing there is very little difference between maximum, minimum, median, and operating band under both scenarios. Differences between Bad Creek II and Baseline scenarios are minor and the largest difference between Baseline and Bad Creek II water levels is observed under CCHigh, as expected.

Spawning performance measures for black bass and blueback herring (under normal hydrology) have seasonal requirements. Lake Jocassee's water surface fluctuation band needs to be held within 2.5 feet during spawning season such that dewatering of nests does not occur. Performance Measures and MISCs¹ were determined in collaboration with relicensing stakeholders (in the summer and fall of 2023) and a 2.5-foot fluctuation band was selected to maximize spawning conditions for targeted fish species. Under the Bad Creek II scenario, there are more years meeting the 2.5-foot fluctuation band restriction than under Baseline operations, which indicates improved chance for spawning success under Bad Creek II operations. For example, Performance Measure 8 is met 100 percent of the time under the Bad Creek II scenario versus 71 percent of the time under the Baseline scenario.

John Hains (via chat) asked why these results were considered surprising. J. Huff clarified she had not expected to see much effect to Lake Jocassee reservoir elevations under Bad Creek II operations. However, considering that Bad Creek operates in tandem with Lake Jocassee, it is actually not surprising water levels would fluctuate within a smaller range. T. Ziegler added since Bad Creek II operations double pumping and generating flows, water pumped up to the UR is essentially being replaced in Lake Jocassee from Lake Keowee. Even though the UR has an increased fluctuation band under Bad Creek II, Lake Jocassee has a smaller fluctuation band.

- J. Huff showed model results for Lake Keowee, demonstrating negligible changes to the max, min, or fluctuation band would be expected under Bad Creek II operations.
- D. Wilde asked why the hydrology data only goes up to 2011. J. Huff answered the hydrology data period of record includes the years 1939 through 2011. The model shifts the hydrology data into the future and then uses the historic rainfall, temperature, and evaporation conditions when it models each operational scenario. Sarah Kulpa mentioned a separate analysis was carried out (prior to modelling for Bad Creek) to ensure updating the hydrology wasn't necessary since it would be a large effort. Results from the sensitivity analysis showed incorporating data from the last 12 years would not add any different extremes for wet and dry years than what are already included in the dataset, therefore, the investment was deemed not worth the return. T. Ziegler and J. Huff added the existing 73-year hydrology dataset includes normal and wet years and also the drought of record for the Savannah River Basin, therefore, it includes the bookends for hydrologic data that can be reasonably expected over the term of the next license, especially when used in conjunction with the two modeled climate change scenarios.
- J. Huff discussed the rate of change for Bad Creek and Jocassee elevation fluctuations. The rate of change in water level fluctuation, or how quickly the reservoir elevation changes, could have implications for boat launching in Lake Jocassee. Therefore, model output was evaluated

¹ Minimum increment of significant change

to see how often fluctuations of >1 foot in 1 hour might occur (representing a very slow boat launch); results showed that would never happen.

Rowdy Harris noted boat ramp use and boat launching is less of an issue than people who tie up a boat at a campground site or hiking trailhead for several hours. They can return to find their boat on dry land with no way to get it back into water. J. Huff reiterated that the model shows approximately 0.5 feet less 24-hour fluctuation under Bad Creek II operations than under the Baseline operations for Lake Jocassee. Therefore, we would expect this would be less likely under the Bad Creek II scenario compared to the Baseline scenario conditions.

J. Hains asked if Jocassee and Bad Creek always operate in tandem. J. Huff explained the model doesn't consider hydro-specific components (like outages, etc.) so there could be a time Bad Creek could operate independently of Jocassee, but generally speaking, they would operate in tandem unless there is some sort of external factor or emergency situation that can't be predicted in a model.

A. Stuart said he talked with Aaron Dale (manager of Duke Energy Operations Group) and he conveyed it would be almost impossible to operate Bad Creek and Jocassee out of sequence (i.e., one hydro pumping while the other generated). There may be occurrences where one hydro may begin pumping or generating before the other, but that would be very a short-term phenomenon and wouldn't be picked up by the CHEOPS model.

- J. Hains asked if there is a scenario where Bad Creek would operate with no operation at Jocassee. A. Scangas noted that scenario was not observed in the CHEOPS model results but could happen for very short time periods as mentioned previously. Planned and unplanned outages or other grid emergencies would be the only likely cases where Bad Creek would operate out of sync with Jocassee, which are events the model cannot incorporate or predict.
- J. Huff explained the goal of the KT LIP is to reduce water losses within the Duke Energy system consistent with the 2014 Operating Agreement and showed days in the KT LIP Stages under the Baseline and Bad Creek II scenarios. Under the Bad Creek II scenario, time (days) in LIP stage zero increases. This is due to the role remaining reservoir storage plays in determining LIP stage. Under Bad Creek II operations, the model releases downstream flows from Keowee that likely would not happen if a human operator were in control. As the model sees Lake Keowee fill, it releases a small amount of water into Lake Hartwell resulting in a small loss of water from the Duke Energy system. These small day-to-day changes in remaining reservoir storage can shift the system from normal LIP stage (i.e., not in the LIP) to LIP stage zero.
- D. Wilde asked for confirmation if the LIP changed in 2011. A. Stuart responded there was no LIP in place prior to 2011, but the 1968 Operating Agreement between Duke Energy, the USACE, and SEPA was in place. Under the 1968 Operating Agreement, Duke Energy was required to release up to 25,000 acre-feet of water per week during droughts. The 2014 Operating Agreement developed during KT relicensing has resulted in a more equitable distribution of water during droughts. S. Kulpa reiterated the 2011 historical dataset is used as a proxy for the future; A. Scangas added historical hydrology is used to simulate under a future lens applying current operating rules. T. Ziegler noted the 1939-2011 hydrology database only

provides the amount of inflow to the Duke Energy and USACE reservoirs - the CHEOPS model layers on the operational instructions and constraints.

The USACE's Lake Hartwell and Thurmond Lake cumulative discharge curves show no difference associated with Duke Energy operations between Baseline and Bad Creek II scenarios.

J. Huff then summarized the study conclusions, opened the floor for more questions, and noted the draft study report was posted on the Relicensing SharePoint site on March 26. Duke Energy kindly requests comments by April 26.

CFD Addendum Discussion

T. Ziegler briefly discussed additional CFD modeling being carried out due to design changes for the proposed Bad Creek II facility (i.e., increased hydraulic capacities due to variable speed vs. single speed pump turbines). This topic was introduced at the Initial Study Report meeting in January 2024. Generation flows increased ~2 percent which would not be dissimilar from flows already modeled using the existing CFD model, however, increased pumping capacity could result in a ~9 percent increase in flows. Therefore, additional pumping flow scenarios were modeled at Lake Jocassee minimum (1,080 feet above mean sea level [ft msl]), full (1,110 ft msl), and intermediate (1,096 ft msl) pond levels.

The CFD model used for this task is the same model used in the feasibility² study as it has a finer resolution that the CFD model used for the relicensing³ study under the Water Resources Study (Task 3).

- D. Wilde asked if there is an overlay image between existing submerged weir vs. the expanded weir. T. Ziegler noted there are figures of both configurations of the weir in the CFD report included in the Initial Study Report and noted the proposed expanded weir crest elevation would stay the same (as the existing weir) and would be expanded in the downstream direction (i.e., towards the main body of Lake Jocassee).
- J. Crutchfield opened the floor for questions or comments.
- J. Hains asked if there are any plans to restrict boating access to Whitewater River cove after construction and operation. A. Stuart said there would be no access restrictions to Whitewater River cove after construction, but Whitewater River cove would be closed during construction. Duke Energy may install a warning cable around the new intake alcove with a buoy system.

² The CFD report for the feasibility study was included with the Revised Study Report in Appendix I.

³ The CFD report for the relicensing study was included with the Initial Study Report in Appendix A.

Action Items

- The draft CHEOPS report has been distributed via the relicensing SharePoint site; comments from stakeholders are requested by April 26, 2024.
- Meeting summary and slide deck will be posted to the SharePoint site in approximately 2 weeks.

Agenda

- Welcome and Meeting Purpose
- Safety Moment
- Task 4 CHEOPSTM Modeling
- Task 3 CFD Modeling
- Adjourn

Bad Creek Pumped Storage Project Joint Resource Committee Meeting | 2

Safety Moment - Road Work Safety

- Summer is the busiest time of year for road work!
- Safety Tips for driving in Work Zones:
 - Pay attention! Eliminate distractions.
 - Be alert for work zone signs and flaggers.
 - · Watch out for road debris.
 - Don't tailgate!!
 - Be patient and obey posted speed limits.
 - The penalty for speeding through a signed work zone is an additional \$250.
 - Don't change lanes.
 - Expect the unexpected: <u>Keep an eye out for workers and their equipment</u>.
 - When possible, use alternate routes or travel at non-peak times to avoid traffic congestion.

Bad Creek Pumped Storage Project Joint Resource Committee Meeting | 5

_

CHEOPS™ (Computer Hydro Electric Operations & Planning Software)

- Hydrologic water quantity simulation model used to evaluate:
 - · Potential economic effects of alternative operations
 - · Upgrades & modifications
 - · Physical & operational changes related to FERC relicensing
- User-definable input data:
 - · Energy production for peak & off-peak periods
 - · Variable durations for daily peak & off-peak periods
 - · Instream or bypass flows in each river reach
 - Water level variation limits in each reservoir or impoundment
 - · Unit performance curves
 - Unit availability
 - · Minimum flows & ramp rates
 - · Hydrology from historical, typical water or calendar

Operations model a software tool for
evaluating a wide
range of physical &
operational
constraints on a
hydroelectric
facility

Bad Creek Pumped Storage Project Joint Resource Committee Meeting | 6

CHEOPS™ & Bad Creek Relicensing

- Scenarios
 - Baseline (existing facilities and FERC license requirements)
 - Alternative: Baseline + Bad Creek II
- Operational effects of scenarios
 - Lake level fluctuations at Bad Creek, Jocassee & Keowee
 - Rate of change in lake levels
 - Low Inflow Protocol (LIP) Stages
 - Keowee Releases to Lake Hartwell

Bad Creek Pumped Storage Project Joint Resource Committee Meeting | 11

69		Number of days in LIP Stage 4	1-Jan	31-Dec		0	35

Summary Conclusions – Bad Creek II Effects

- Bad Creek Reservoir elevation: Wider operating band
- Lake Keowee and Lake Jocassee elevations: Comparable to Baseline
- Lake Jocassee reservoir level fluctuations rate of change (24-hour period): Smaller than Baseline
- Lake Keowee water intakes: No effect
- Keowee-Toxaway Low Inflow Protocol (LIP)
 - Stage 0 frequency increases
 - Differences diminish in the more advanced stages of the KT LIP
- USACE reservoirs, Savannah River flows: Minimal effect

Bad Creek Pumped Storage Project Joint Resource Committee Meeting | 23

23

Next Steps

- Review draft study report
 - Posted to SharePoint site
 - Comments due: April 26, 2024

Additional CFD Modeling – Overview

- Additional CFD modeling is ongoing to incorporate recent design changes (from single-speed to variable speed turbines) at Bad Creek II, which will result in slightly higher hydraulic capacities than originally modeled
- Generation flows will increase by just ~2 percent while flows under pumping will increase by ~9 percent; therefore, only updated pumping capacities will be modeled
- Three scenarios will be modeled: full pond (1,110 ft msl), max drawdown (1,080 ft msl), and intermediate (1,096 ft msl); these elevations are consistent with those modeled during the feasibility study
- Because focus is on near-field flows (i.e., vicinity of inlet/outlet structure), the same CFD model used for the **feasibility study** will be used for updated modeling instead of the CFD model used for the relicensing study (which focused on flows downstream of the weir)
- Findings will be drafted **as an addendum** to the previous CFD Report and will be distributed to stakeholders for review in Q2

Bad Creek Pumped Storage Project Joint Resource Committee Meeting | 27

27

Previous Results (Feasibility Study) - Existing Operations

Similar figures will be developed for updated pumping at Bad Creek II with proposed I/O structure

Existing I/O Pumping at 1,110 ft msl

Existing I/O Pumping at 1,080 ft msl

Subject: Bad Creek Relicensing - CHEOPS Modeling Draft Report Ready for Review and April 4 Meeting Agenda

Cc: Lineberger, Jeff < Jeff.Lineberger@duke-energy.com >; Sarah Kulpa < Sarah.Kulpa@hdrinc.com >;

Dear Bad Creek Resource Committee members:

Angie.Scangas@hdrinc.com; Ziegler, Ty <tv.ziegler@hdrinc.com>

Duke Energy is pleased to distribute the draft Water Resources – Task 4 (i.e., CHEOPS Modeling) report for your review. This draft includes the results from CHEOPS modeling for the Baseline and Bad Creek II scenarios as well as populated Performance Measures sheets. The draft report is available on the SharePoint site using this link: Bad Creek Relicensing Project – Resource Committees - Draft CHEOPS report - All Documents (sharepoint.com).

Please provide your comments within the draft report using Track Changes as explained further below within 30 days (**April 26, 2024**). When you have completed your review – even if you have no comments – I would appreciate an email stating that is the case.

<u>Important – Please Read!</u>

 As discussed in the kick-off meeting (July 2022), Duke Energy is providing relicensing deliverables on the SharePoint site for relicensing participants to access, review, and comment on files. Please <u>provide all</u> <u>comments in the SharePoint Word document using tracked changes</u>. This will eliminate version control issues,

- enable relicensing participants to gain insight into one another's comments, and result in a consolidated document for comment response.
- We strongly recommend opening the document in Word; otherwise the formatting will look distorted. The
 simplest way to do this is to click on the three dots to the right of the document (example shown below),
 choose "Open", then choose "Open in app". This will open the document in Word and you'll have the
 functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free
 to reach out to @McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word – either technique works!])

We will be discussing the draft report and report findings during the April 4, 2024, Joint Resource Committee meeting. I have attached the meeting agenda for your reference.

If you have questions, please contact Alan Stuart or me.

Regards,

John Crutchfield

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Resource Committee members:

The CHEOPS modeling report has been finalized and can be accessed at the Bad Creek Relicensing SharePoint site:

20240326 Bad Creek CHEOPS Final Report.pdf

Please let Alan or me know if you have any questions.

Regards,

John Crutchfield

Subject: Bad Creek Relicensing - Bad Creek CFD Model Updated Pumping Rates Draft Addendum (REVIEW REQUESTED)

Date: Wednesday, June 12, 2024 11:58:09 AM

Attachments: image001.png image002.png

Importance: High

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Resources Committees:

Duke Energy is pleased to distribute the **Bad Creek CFD Model Updated Pumping Rates Draft Addendum** for Resource Committee review. This draft report is the second addendum to the Task 3 final report (*Velocity Effects and Vertical Mixing in Lake Jocassee Duke to a Second Powerhouse*), which was filed with the Initial Study Report in January of this year. The purpose of the addendum is to provide results of additional CFD modeling performed to incorporate increased hydraulic pumping at Bad Creek II from a recently proposed technology modification (variable speed pump-turbines vs. single speed). The deliverable is available on the Bad Creek Relicensing SharePoint site at the following link: Addendum 2_Updated Pumping CFD Model Report. Duke Energy is requesting a 30-day review period, therefore, please submit all comments by **July 12**. A confirmation email is kindly requested upon review completion (email me at John.Crutchfield@duke-energy.com).

Important – Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables
 available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment;
 therefore, we request all comments be made in the SharePoint Word document using tracked changes. This
 will eliminate version control issues and result in a consolidated document for comment response.
- We strongly recommend opening the document in Word; otherwise, the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (example shown below), choose "Open", then choose "Open in app". This will open the document in Word, and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word — either technique works!])

Also, please note this draft report addendum is being sent to the Water Resources, Aquatics, Operations, and Recreation & Visual Resource committees, and you may receive multiple emails if you are on several of these committees' distribution lists. I apologize in advance if you get multiple emails.

If you have any questions, please contact Alan Stuart or me.

Regards,

John Crutchfield

Good Morning John,

I have finished my review of the report and as I think I mentioned to Alan at an earlier date, I believe the modeling for this is good and I have criticism neither of the way it was done, nor of the report and addendum.

However, when subsequent field studies have commenced in order to confirm the predictions of the model, I stand by my request to make before/after field data from Lake Jocassee available. It would also be useful in that analysis to revisit the before/after operational lake data for Bad Creek I...for the purpose of making a complete comparison between the proposed project and the way the lake responded to the original project.

I will be glad to discuss this further with you if that is needed.

Best,

John Hains

Subject: Bad Creek Relicensing - Bad Creek CFD Model Updated Pumping Rates Draft Addendum (REVIEW REQUESTED)

Dear Bad Creek Relicensing Resources Committees:

Duke Energy is pleased to distribute the **Bad Creek CFD Model Updated Pumping Rates Draft Addendum** for Resource Committee review. This draft report is the second addendum to the Task 3 final report (*Velocity Effects and Vertical Mixing in Lake Jocassee Duke to a Second Powerhouse*), which was filed with the Initial Study Report in January of this year. The purpose of the addendum is to provide results of additional CFD modeling performed to incorporate increased hydraulic pumping at Bad Creek II from a recently proposed technology modification (variable speed pump-turbines vs. single speed). The deliverable is available on the Bad Creek Relicensing SharePoint site at the following link: Addendum 2_Updated Pumping CFD Model Report. Duke Energy is requesting a 30-day review period, therefore, please submit all comments by **July 12**. A confirmation email is kindly requested upon review completion (email me at John.Crutchfield@duke-energy.com).

Important - Please Read!

• As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment;

- therefore, we request all comments be made in the SharePoint Word document using tracked changes. This will eliminate version control issues and result in a consolidated document for comment response.
- We strongly recommend opening the document in Word; otherwise, the formatting will look distorted. The
 simplest way to do this is to click on the three dots to the right of the document (example shown below),
 choose "Open", then choose "Open in app". This will open the document in Word, and you'll have the
 functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free
 to reach out to @McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word — either technique works!])

Also, please note this draft report addendum is being sent to the Water Resources, Aquatics, Operations, and Recreation & Visual Resource committees, and you may receive multiple emails if you are on several of these committees' distribution lists. I apologize in advance if you get multiple emails.

If you have any questions, please contact Alan Stuart or me.

Regards,

John Crutchfield

Subject: Bad Creek Relicensing - Bad Creek CFD Model Updated Pumping Rates Draft Addendum (REVIEW REQUESTED)

Importance: High

Dear Bad Creek Relicensing Resources Committees:

Duke Energy is pleased to distribute the **Bad Creek CFD Model Updated Pumping Rates Draft Addendum** for Resource Committee review. This draft report is the second addendum to the Task 3 final report (*Velocity Effects and Vertical Mixing in Lake Jocassee Duke to a Second Powerhouse*), which was filed with the Initial Study Report in January of this year. The purpose of the addendum is to provide results of additional CFD modeling performed to incorporate increased hydraulic pumping at Bad Creek II from a recently proposed technology modification (variable speed pump-turbines vs. single speed). The deliverable is available on the Bad Creek Relicensing SharePoint site at the following link:

<image001.png>

<u>Addendum 2_Updated Pumping CFD Model Report</u>. Duke Energy is requesting a 30-day review period, therefore, please submit all comments by <u>July 12</u>. A confirmation email is kindly requested upon review completion (email me at <u>John.Crutchfield@dukeenergy.com</u>).

Important – Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document using tracked changes. This will eliminate version control issues and result in a consolidated document for comment response.
- 2. We strongly recommend opening the document in Word; otherwise, the formatting will look distorted. The simplest way to do this is to click on the three dots to the right of the document (example shown below), choose "Open", then choose "Open in app". This will open the document in Word, and you'll have the functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free to reach out to @McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides

an alternative way to open the document in Word – either technique works!])

<image002.png>

Also, please note this draft report addendum is being sent to the Water Resources, Aquatics, Operations, and Recreation & Visual Resource committees, and you may receive multiple emails if you are on several of these committees' distribution lists. I apologize in advance if you get multiple emails.

If you have any questions, please contact Alan Stuart or me.

Regards,

John Crutchfield

John,

Due to workload and not having expertise in this type of model the Service will not be reviewing and will defer to other Resource Committee's members for their expertise and comments.

Subject: [EXTERNAL] Bad Creek Relicensing - Bad Creek CFD Model Updated Pumping Rates Draft Addendum
(REVIEW REQUESTED)
```

This email has been received from outside of DOI - Use caution before clicking on links, opening attachments, or responding.

Dear Bad Creek Relicensing Resources Committees:

Duke Energy is pleased to distribute the **Bad Creek CFD Model Updated Pumping Rates Draft Addendum** for Resource Committee review. This draft report is the second addendum to the Task 3 final report (*Velocity Effects and Vertical Mixing in Lake Jocassee Duke to a Second Powerhouse*), which was filed with the Initial Study Report in January of this year. The purpose of the addendum is to provide results of additional CFD modeling performed to incorporate increased hydraulic pumping at Bad Creek II from a recently proposed technology modification (variable speed pump-turbines vs. single speed). The deliverable is available on the Bad Creek Relicensing SharePoint site at the following link: Addendum 2_Updated Pumping CFD Model Report. Duke Energy is requesting a 30-day review period, therefore, please submit all comments by **July 12**. A confirmation email is kindly requested upon review completion (email me at John.Crutchfield@duke-energy.com).

Important - Please Read!

- As discussed in the kick-off meeting (July 2022), Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the SharePoint Word document using tracked changes. This will eliminate version control issues and result in a consolidated document for comment response.
- We strongly recommend opening the document in Word; otherwise, the formatting will look distorted. The
 simplest way to do this is to click on the three dots to the right of the document (example shown below),
 choose "Open", then choose "Open in app". This will open the document in Word, and you'll have the
 functionality you are accustomed to. Your changes will be saved automatically as you review. Please feel free
 to reach out to McCarney-Castle, Kerry for SharePoint assistance.

(Note: If you are new to SharePoint, a very brief tutorial with screenshots is available on the home page of the Resource Committees tab called "Editing a Document in SharePoint". This is the same tutorial that was presented during the kick-off meeting. [The tutorial provides an alternative way to open the document in Word — either technique works!])

Also, please note this draft report addendum is being sent to the Water Resources, Aquatics, Operations, and Recreation & Visual Resource committees, and you may receive multiple emails if you are on several of these committees' distribution lists. I apologize in advance if you get multiple emails.

If you have any questions, please contact Alan Stuart or me.

Regards,

John Crutchfield

Dear Bad Creek Relicensing Resources Committees:

Duke Energy is pleased to distribute the final **Bad Creek CFD Model Updated Pumping Rates Addendum** for your reference. This report will be included with the Updated Study Report as an addendum to the Task 3 report (i.e., Velocity Effects and Vertical Mixing in Lake Jocassee Due to a Second Powerhouse Report), which was finalized last year and filed with the Initial Study Report. The addendum will also be filed with FERC as an attachment to the sixth Quarterly Progress Report.

You can access the final addendum at the link given below:

Addendum 2 Updated Pumping CFD Model Report

If you have any questions, please contact Alan Stuart or me.

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Bad Creek Relicensing Water Resources Committee:

Duke Energy is pleased to distribute the <u>Water Quality Monitoring in Whitewater River Arm</u> draft report for Resource Committee review. This draft report satisfies Task 2 of the Bad Creek Relicensing Water Resources Study and presents results of continuous and bi-weekly water quality monitoring at three locations in the Whitewater River arm over two study seasons (June-Sept 2023 & 2024) to provide additional information on the function of the submerged weir and vertical mixing as well as baseline conditions under recently upgraded Project operations. The deliverable is available on the Bad Creek Relicensing SharePoint site at the following link: Task 2 - Water Quality Monitoring in Whitewater River Arm. Duke Energy is requesting a 30-day review period, therefore, please submit all comments by **November 25th**. A confirmation email is kindly requested upon review completion (email me at John.Crutchfield@duke-energy.com).

Important - Please Read!

- Duke Energy would like to make relicensing deliverables available on a shared platform (i.e., SharePoint) so all stakeholders can access, review, and comment; therefore, we request all comments be made in the <u>SharePoint Word document using tracked changes</u>.
